SUPPLEMENT TO "THE ELECTRICIAN," NOVEMBER 3, 1893.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

VOLUME XXXI.

FROM MAY 5, 1893, TO OCTOBER 27, 1893.

LONDON:
Printed and Published for the Proprietors by GEORGE TUCKER, at the Offices of "THE ELECTRICIAN," Salisbury-court, Fleet-street, E.C.

1893.

INDEX TO "THE ELECTRICIAN."

VOL. XXXI.

General Alphabetical Index.

Italic figures denote that the subject matter is in the "LEADING ARTICLES" or in the "EDITORIAL NOTES."

A

Absorption of Energy, The, 465
Accidents, 279, *504*, (*Leeds*) 434, (*Blackfriars*) *514*, 548, (*to Helmholtz*) *659*
Actinometer, An Electro-Chemical, 254
Adams Memorial Tablet, The, 115
Alternate-Current Motors, *1*, 30, 253, *571*, 590, 618, 626
Alternate-Current Motor Controversy, 17, *55*, 58, 171, 269
Alternate-Current Transformers: by Dr. W. E. Sumpner, 197
Alternate-Current Wiring: by W. D. Weaver, 651
Alternate Currents from Influence Machines, 435
Alternating Electric Currents, The Practical Measurement of: by Prof. J. A. Fleming, 447, 476, 505, 533

Alternators—
Low Frequency at Derby, *632*
Parallel Working, 344
Pulvermacher High-Frequency, *88*
Pyke-Harris, *27*

Aluminium Reduction and the Niagara Falls Power Company, 304
Aluminium Solders and Alloys, 46, 708
Ambiguity in Science, *668*
American Electric Locomotive, An, *332*, 344, *600*
American Institute of Electrical Engineers (Meeting of), 651
American Philosophical Society, 88
Ampère's Table, A Novel Arrangement for, 447
Ampère, The Town of, 89, 626
ANDERSON, Dr. WILLIAM: Interdependence of Abstract Science and Engineering, The, 39, 72
Andreoli Ozonizer, *355*
Antwerp Exhibition, 19
Arago, Statue of, 168
Arc, Electric, Behaviour of, under Pressure: by Dr. Louis Duncan, *355*, 360
Arc, Electric, Fusion and Volatilisation of Various Substances in: by H. Moissan, 285
Arc, Electric, The Light of the: by M. Violle, 259

Arc Lamps—
Accidents, 279
Arc Lamps and Incandescent Gas Burners, 293
Brush-Adams Clutch, 540
Candle Power, 89, 322
Harp Lamp, The, 169
Inverted, for Workshop Lighting, *687*, 701
Marks Lamp, The, *487*, 502
Maximum Efficiency of: by Prof. H. S. Carhart, *600*, 621
New Street Post, 311
Placing of Arc Lamps, *459*, 464

Armature Current, The Reaction of, upon the Field: by J. Fischer-Hinnen, 104
Armature Winding, A New, 365
Armatures, Calculating, *304*
ARMSTRONG, Prof. HENRY E.:
Conditions Determinative of Chemical Change, 228
Nature of Depolarisers, 229, 539
ARNO, RICCARDO:
On the Dissipation of Energy in a Rotating Electric Field and on Electrostatic Hysteresis, 201
On the Transparency of Ebonite, 371
Arsenic, Removing, from Copper, 280
Arsenic, Testing for, 305
Artificial Draught, 388
Auction Bids by Telephone, 270
Australian Electric Light and Power Wire Regulations, 244
Averages, *442*
AYRTON, Prof. W. E.: "New Lamps for Old," 585
Azores Cable, The, 115, (*Concession Signed*) 167, (*Cable Laid*) 475

B

BAKER, Sir BENJAMIN: Theory and Practice, 41
Balancing of Reciprocating Mechanism, *546*, 562
Barrack Yards, Electric Lighting of, 195
BASSET, A. B.: Electro-Optics, 425

Batteries (Primary)—
Clark Standard Cells, Instructions for Repairing, 265
Cooper, W. R., on—*see* Cooper
Measurement of Internal Resistance, 263

Batteries (Secondary)—
Consumers' Houses, Secondary Batteries in, *166*
Faure Patent in France, The, *165*, 170
Faure Patent in the United States, 372
German Patent Decision, 682

BEACH, FREDERICK E.: The Use of Cupric Nitrate in the Voltameter and the Electro-Chemical Equivalent of Copper, 466
Bearing Cooling, 386
BEAUMONT, W. WORBY:
Balancing of Reciprocating Mechanism, *546*, 562
Variable Gear, *571*, 586
BEHN-ESCHENBURG, Dr.: A Simple Apparatus for Comparison of the Magnetic Qualities of Samples of Iron 417
Belts, Paper, 522
Bessbrook-Newry Railway, The Accident on the, 4
Bicycle Electric Railway, 253
Blackwood, Sir A., *599*
BLONDEL, ANDRÉ:
Electric Light of Lighthouses, On the, 478
Measurement of Self-Induction, 601
BLOUNT, BERTRAM:
Accuracy of the Copper Voltameter, 59
Electrolysis at Definite Electrical Pressures, 494
Board of Trade Appointments, 88
Board of Trade Regulations with Regard to the Earthing of Transformers, 222
Bodländer Electrolysis, *600*
Bogus Electric Light Men, 708
Boiler Explosions, 195
Boiler Testing: by W. Geipel and H. Kilgour, 397
Boltzmann on the Relation of Graphic and Model Representations to Physical Hypotheses, 254
BOTTOMLEY, J. T.: Thermal Radiation in Absolute Measure, 95
Boyle, Sir Courtenay, *55*
BRANLY, E.: On the Dissipation of Electricity by Diffused Light and in the Dark, 94
Brewer's Exhibition, 708

British Association (Nottingham), *487*, *546*
Glazebrook's (Mr.) Presidential Address, *513*, 534
Grants, 547
List of Papers read, 557
Papers read before—*see* Societies' Meetings
Proposed Arrangements for 1894 and 1895, 548
Report of Committee on Electrical Standards, 552
Resumé, 558

British Museum Lighting, The, 88, 515
Brush 125-Arc Light Machine, 652
Bullets, Photographing Flying, 410

C

Cable Interruptions and Restorations, 3, 57, 89, 115, 141, 166, 194, 220, 252, 279, 304, 333, 386, 434, 460, 489, 515, 547, 572
Cables, New: Azores, 115, 167, 475; Mauritius, 115; Queensland, 678, 689
Cadmium Mercury Cell: by Arthur Dearlove, 645
California (Proposed Exposition), 633
Cambridge, Engineering at, 90
Campiche's Electrically-Propelled Pendulum, 633
Canadian Electrical Association, 515, 661
Canals, Electric Traction on, 29, 195, 411
Candelabrum, A Large Electric, 489
Carbon, The Specific Heat of, 196
Carburation of Iron by Electricity, *220*, 227
CARHART, Prof. H. S.: Maximum Efficiency of Arc Lamps, *600*, 621
CARTER, E. TREMLETT: Price of Electric Supply, 145
"Cartesian" Ammeter, The, 461
"Castle" Dynamo, A Large, 102, *114*
Ceiling Roses, 46
Cell Tester, The Holden, 200
Cement for Steam Pipes, 356
Central Institution, The, 29
Central London Railway Central Railway Station at the Mansion House, 168, 279
Central Meat Markets, Lighting of, 271
Central Station Contracts, 78
Central Stations in Crowded Districts, *219*, *304*
Central Stations in France, 387
Central Stations, Small, 268
Chapel and Church Lighting, 595, 709
Chappe, A Statue to, 89, 306
Charles' Law and the Gas Bills, 461
Cheap Traction or Defective Telephones, 69
Chemical Change, Conditions Necessary for, *220*, 228
Chemistry, Some Applications of Electricity to: by James Swinburne, 7

Chicago Exhibition—
American Institute of Electrical Engineers and Institution of Electrical Engineers, 116
American Society of Civil Engineers and Institution of Electrical Engineers, 3
Awards: The Thacher System of, *115*; British, 689
Commercial Rivalries, 280
Congress—*see* Congress (International Electrical)
Cost of, 548
Electrical Engineers of England, The, and the Exhibition, *29*
Electricity at the Exhibition, 45
English Electrical Section, The, *1*
Intramural Railway, 93
Judges, *356*, 358, 410
Lighting of, 689
Moving Sidewalk, 683
Opening, 77, *88*
Tests of Lamps at, *601*, 622, *651*, 654
Weston Instruments, 489

Chimatto Enamel, 541
Chodat, Prof. R., on the Action of Electric Light on Vegetation, 634
CHRISTIE, W. M.: Dynamo Shielding, 446, *455*
Church Bells *v.* Electric Fire Alarm Bells, 484
City and Guilds Diplomas, The, 357
City and Guilds Technological Examinations, The, 89
City and South London Railway, (*Fares*) 305, *331*, *355*, 387, 399, (*Breakdown*) 410, (*Dr. E. Hopkinson's Paper on*) 582
Clark Standard Cell, (*Instructions for Preparing*) 265, (*Rival Forms*) 441, 515
Claude Phasemeter, 229
Clocks, Electrically Controlled, on Lighting Mains, 253
Coal (*Coast Engine*) 490, (*Smokeless Combustion*) 602, (*Japanese*) 601
Coast Communication, (*U.S.A.*) 573, (*East Coast*) 573, (*S.E. Coast*) 661

COMPANIES' MEETINGS, REPORTS, DIVIDENDS, STATUTORY RETURNS, &c.

(Abbreviations:—Mtg., Meetings of Shareholders Rpt., Reports of Directors; Div., Dividend; Rev., Revenue; Stat., Statutory Returns.)
Abell's Electrical Engineering Company—541
African Direct Telegraph Company—53, 217; Stat., 457
African Trans-Continental Telegraph Company—Mtg., 24, 53; Stat., 137
Akester Electro-Motor and Accumulator Company—Stat., 457
Albert Electric Lighting Company—Stat., 137
A. U. Alcock Electric Light and Motive Power Company—Mtg., 667
Allen, Everett and Sons—Stat., 383
Alliance Aluminium Company—111
American Insulated Wire Company—485
Andrew (J. E. H.) and Co.—Stat., 85
Andrews and Preece—Stat., 329
Anglo-American Telegraph Company—Rpt., 326; Div., 329, 597; Mtg., 376
Anglo-Portuguese Telephone Company—Stat., 85, 249
Arc Accumulator Company—485
Arcas Plating Company—249
Art Workshops—452
Askwith and Co.—Stat., 137
Atlas Carbon Manufacturing Company—Stat., 485
Automatic Electric Railway Signal Company—Stat., 137
Automatic Electrical Corporation—301
Automatic Standard Screw Company—541
Australasian Electric Light, Power and Storage Company—217
Babcock and Wilcox—457; Stat., 637
Baily, Grundy and Barrett—Stat., 301
Barnet and District Electric Supply Company—Stat., 301
Benham and Froud—Stat., 163
Bernstein Electric Lamp Company—85
Bickle and Co.—Stat., 657
Birmingham Central Tramways Company—189; Rpt., 407; Div., 457
Birmingham Electric Supply Company—Stat., 85
Birmingham House-to-House Electricity Company—Stat., 163
Birmingham Mint—Div., 191
Boardman's Electric Sun Lamp Patents—Stat., 485

COMPANIES' MEETINGS, &c. (*continued*).—

Boy Messengers and Electric Call Company—111
Brazilian Submarine Telegraph Company—Mtg., 21 684; Div., 137; Stat., 163, 217, 326
Brighton and Hove Electric Light Company—711
British Electric Tramways and General Syndicate—Stat., 485
British Gas Engine and Engineering Company—595
British Tanning Company—52
British Volta Electric Glow Lamp Company—657
Browett, Lindley and Co.—Stat. 301
Brush Electrical Engineering Company—Stat., 191; Rpt., 431; Mtg., 455
Callender's Bitumen Telegraph and Waterproof Company—Stat., 301: Div., 711
Cambridge University and Town Electric Lighting Company—329
Central London Railway Company—217, 249
Chamberlain and Hookham—Stat., 85
Charing Cross and Strand Electricity Supply Corporation—Div., 353
Chatham, Rochester and District Electric Lighting Company—249, 275
Chelsea Electric Supply Corporation—25; Stat., 329
Chili Telephone Company—Rpt., 352; Mtg., 377; Stat., 657
China and Japan Telephone Company—Mtg., 84; Stat., 329
Chloride Electrical Storage Syndicate—Stat., 657
City and South London Railway Company—Rev., 25, 53, 85, 111, 137, 163, 191, 217, 249, 273, 301, 329, 352, 353, 383, 407, 431, 457, 485, 511, 543, 569, 597, 629, 657, 685, 711; Mtg., 378
City of Bath Electric Lighting and Engineering Company—Stat., 25
City of London Electric Lighting Company—Stat., 85, 217; Div., 249, 407
Column Printing Telegraph Syndicate—Stat., 657
Commercial Cable Company - Div., 191, 544
Compagnie Belge du Téléphone Bell - 301
Consolidated Telephone Construction and Maintenance Company—25, 52; Div., 53; Mtg., 188
Continental Electric Dividends—711
Continental Metropolitan Tramways Company—25
Corlett Electrical Engineering Company—Stat., 685
Crompton and Co.—Rpt., 353; Mtg., 381
Crompton-Howell Electrical Storage Company—Stat., 329
Croydon Tramways Company—457
Crystal Palace District Gas Company—543
Cuba Submarine Telegraph Company—Rev., 25, 163 275, 511, 629; Div., 383; Rpt., 407; Mtg., 429
Cutting (R. C.), Douglass and Co.—Stat., 137
Cuttriss, Wallis and Co.—Stat., 329
Dalziel's Atlantic Telegram Company—Stat., 329
Danks (Walter) and Co., 301
Dan Rylands—191
Dawson (R.)—Stat., 137
Dick, Kerr and Co.—Stat., 25
Direct Spanish Telegraph Company—Stat., 25; Rev. 25, 53, 275, 407, 431, 511, 629; Div., 353; Rpt., 456, 485; Mtg., 510
Direct United States Cable Company—Rpt., 326; Div., 329, 657; Mtg., 375
District Messenger Company of Paris—353
District Messenger Service and News Company—191
Domestic Telephone Company—Stat., 685
Dominion Electrical Company—Stat., 85
Dublin United Tramways Company—353
Eastbourne Electric Light Company—Stat., 353
Eastern and South African Telegraph Company—191; Stat., 569, 629
Eastern Extension, Australasia and China Telegraph Company—Rev., 25, 275, 383, 511, 629; Div., 249, 569; Stat., 191: Rpt., 710
Eastern Telegraph Company—Rev., 25, 137, 163, 275, 383; Div., 249, 568, 629; Rpt., 274; Mtg., 299, 323, 329, 485, 511;

Woking Electric Supply Company—Stat., 25
Woodhouse and Rawson Electric Manufacturing Company—53, 85
Wyndham Electric Light Company—275
Wynne's Electric Closed-Tube Tramways—Stat., 457
Yorkshire House-to-House Electricity Company—Rpt., 24; Mtg., 84; Stat., 163, 276

COMPANIES (NEW ELECTRICAL, &c.) REGISTERED—

The following Companies have been Registered under the Limited Liability Acts during the past half-year:—

Adams (Geo.) and Sons, 711
Aladdin Primary Electric Battery Company, 25
Anderson, Anderson and Anderson, 543
Arrol (Sir William) and Co., 191
Bellis (G. E.) and Co., 383
Bindley's, 275
Bourne and Grant Electricity Supply Company, 85
British Volta Electric Glow-Lamp Company, 511
Caledonian Electric Supply Company, 301
Calvert and Co., 569
Canterbury Electricity Company, 711

Digitized by Google

COMPANIES, NEW ELECTRICAL, &c., REGISTERED (*continued*)—
Carmichael and Co., Jas., 329
Catterson (S. P.) and Sons, 456
Chemical and Electrolytic Syndicate, 543
Clark (Frank W.) and Co., 383
Clarke, Chapman and Co., 216
Colne Engineering Company, 52
Coventry Electric Tramways, 85
Cowdy (Jeremiah) and Co., 569
Daimler Syndicate, 191
District Messenger Company of Paris, 353
Dolgorouky Copper Mines and Smelting Company, 511
Dover Electricity Company, 711
Electric and Automatic Engineering Company, 329
Electric Construction Company, 353
Electro-Protector Syndicate, 569
Elektricitäts-Aktiengesellschaft vormals Schuckert und Co. (Nurnberg), 216
Elektricitäts-Gesellschaft Gelnhausen, 25
English Electric Manufacturing Company, 711
Erste Ungarische Elektricitats Aktien-Gesellschaft, 216
Europe and Azores Telegraph Company, 456
Faraday Electrical Engineering Company, 597
Ford-Lloyd Manufacturing Company, 191
Forster (John) and Co., 597
Foster Bros., 191
Gardiner, Sons and Co., 431
General Electrolytic Parent Company, 383
Gravier Dynamo Syndicate, 329
Harrison, Ainslie and Co., 543
Hart, Son, Peard, and Co., 711
Hendry (Geo.) and Co., 25
Incandescent Electric Lamp Company, 383
Industries and Iron, 191
Lamina Accumulator (Elieson's British Patents) Syndicate, 275
Manchester Steel Nut and Tube Company, 329
Marchant, Young and Co, 569
Marine Signals (Barker's) Syndicate, 456
Merionethshire Electric Lighting, Power, and Appliance Company, 191
McInnes (T. S.) and Co., 485
Muir, William, and Co., Manchester, 711
North-Eastern Telephone Company, 249
Northern Steel and Hardware Company, 301
Omnibus and Tramcar Electric Lighting Company, 629
Orme's Electric Signal Syndicate, 216
Parnall (William) and Co., 216
Perkins and Bellamy, 25
Pioneer Electric Carriage Company, 191
Poore (Richard) and Co., 191
Rainbow Engineering Company, 25
Ramsden, Camm, and Co., 711
Robinson (Thos.) and Son, 52
Rollason's Wind Motor Company, 52
Rotherham Forge and Rolling Mills Company, 569
St. Nicholas Construction Company, 54
Salt Lake and Ogden Gas and Electric Light Company, 216, 249
Saxby and Farmer, 52
Shillingford Works Company, 569
Société Industriellé des Téléphones, 685
Stannum Metal Company, 329
Swan and Harrison Smelting Company, 657
Thompson Brothers, 85
United Gutta-Percha and Rubber Company, 217
Valveless Gas Engine Syndicate, 249
Waterhouse Electro-Metric Syndicate, 456
West Hampstead Foundry and Engineering Company, 85
West Indian Development Company, 329
Wolverton and Stony Stratford District New Tramway Company, 569
Zohrab and Biggs English Patents, 25
Compass Disturbances, 195
Compensating Generators at Derby: by W. B. Sayers, 677
Condensers and Choking Coils on Alternating Circuits, *303*, 307, *331*
Condensers and Idle Currents of Transformers: by Prof. J. Perry, 359
Congress (International Electrical), 524
English Delegates, 88, 356
Light (Unit of), 592
Official Delegates, List of, 515
Papers Read, List of, 516—*see* Societies' Meetings
Preliminary Programme, 151
Summary of Proceedings, 522
Thompson, Prof. Silvanus P., on the Congress, 577
Continuous Control of Electric Light Cable Systems: by M. Kallmann, 103

Scientific Societies—Papers, &c., read before.

Académie des Sciences.
On the Dissipation of Electricity by Diffused Light and in the Dark, 94 — BRANLY, EDOUARD.
Fusion and Volatilisation of Various Substances in the Electric Arc, 285 — MOISSAN, H.

Accademia Gioenia di Cattania.
A Contribution to the Theory of Alternate-Current Electrolysis, 258 — MALAGOLI, RICCARDO.

British Association.
Air Pump, 588 — THOMSON, Prof. J. J.
Application of Electrolysis to Qualitative Analysis, 608 — KOHN, Dr. C. A.
Automatic Balancing of Reciprocating Mechanism, 562 — BEAUMONT, W. W.
Electrical Standards Committee, Report of, 552 — GLAZEBROOK, R. T. (*Sec.*)
Graphic Methods, Committee's Report of, 552 — HELE-SHAW, Prof. H. S. (*Sec.*)
Piezo-Electric Property of Quartz, 561 — Lord KELVIN.
Piezo-Electric Pile, 562, 664 — Lord KELVIN.
Presidential Address, Section A, 543 — GLAZEBROOK, R. T.
Self-Exciting Armatures for Continuous-Current Dynamo-Electric Machines and Compensators for Loss of Pressure in Feeders of Electric Supply Mains, 563 — SAYERS, W. B.
Sensitive Ballistic Galvanometer, 622, A — LODGE, Prof. O.
Standards of Low Resistance, 620 — JONES, Prof. VIRIAMU.
Water-Power, Utilisation of Waste, 505 — SNELL, A. T.

Cleveland Electric Club.
Rail-Bonding, 201 — WASON, C. W.

Chemical Society.
Conditions Determinative of Chemical Change, 228 — ARMSTRONG, HENRY E.
Nature of Depolarisers, 229, 539 — ARMSTRONG, HENRY E.

Chicago Congress.
Direct Current Dynamos of very high Potential, 703 — CROCKER, F. B.
Iron for Transformers, 623 — EWING, Prof. J. A.
Maximum Efficiency of Arc Lamps, The, 621 — CARHART, Prof. H. S.
New Incandescent Arc Lamp, 502, A — MARKS, L. B.
Ocean Telephony, 439, 473 — THOMPSON, S. P.
Temperature Variation of Resistance of Copper, 624 — KENNELLY, A. E., and FESSENDEN, R. A.

Elektrotechnischer Verein.
Continuous Control of Electric Light Cable Systems, 103 — KALLMANN, M.

Institution of Civil Engineers.
Interdependence of Abstract Science and Engineering, 38, 72 — ANDERSON, WILLIAM.

Institution of Mechanical Engineers.
Electric Rock-Drilling Machinery, 401 — STEAVENSON, A. G.
The Artificial Lighting of Workshops, 701 — DOBSON, B. A.

Incorporated Gas Institute.
Electric Lighting, 181, 204 — LANE, DENNY.

Institution of Electrical Engineers.
Distribution of Power by Alternate-Current Motors, *Discussion*, 13. — SNELL, ALBION T.
A New Form of Portable Photometer, 42. *Discussion*, 44 — SALOMONS, Sir DAVID
Note on a Detail in Parallel Working of Alternators, 344 — MORDEY, W. M.
On the Prevention and Control of Sparking; Continuous Current Dynamos without Winding on the Field-Magnets, and Constant Pressure Dynamos without Series Winding, 60. *Discussion*, 128 — SAYERS, W. B.
Primary Batteries in Theory and Practice, 636, 674, 692 — COOPER, W. R.

International Maritime Congress.
On the Electric Light of Lighthouses, 478 — BLONDEL, A.

National Electric Light Association.
On Light and other High-Frequency Phenomena, 152, 176 — TESLA, NIKOLA.

New England Waterworks Association.
The Electrolysis of Water Pipes, 172 — MORSE, C. H.

Philosophical Society of Glasgow.
Lord Kelvin's New Electricity Meters, 421 — MEIKLE, A. W.

Physical Society.
Influence Machine, An, 241 — WIMSHURST & PIDGEON
Instruments Exhibited: (*Nalder Bridge and Commutator*) 241; (*Paul Low Resistance Voltameter*) 242
Long-Distance Telephony, 242 — PERRY, J.
Luminous Discharges in Electrodeless Vacuum Tubes, 14. *Discussion*, 16 — RIMINGTON, E. C.
New Photometer, A, 173 — TROTTER, A. P.
Some Notes on Photometry, 173 — THOMPSON, S. P.

Reale Accademia delle Scienze di Torino.
On the Transparency of Ebonite, 371 — ARNÒ, RICCARDO.

Reale Accademia dei Lincei.
On the Dissipation of Energy in a Rotating Electric Field, and on Electrostatic Hysteresis, 201 — ARNÒ, RICCARDO.

Royal Society.
Magnetic Viscosity, 69 — HOPKINSON, J.; LYDALL, F.; WILSON, E.
Thermal Radiation in Absolute Measure, 95 — BOTTOMLEY, J. T.
Electrolysis of Steam, 290, 316 — THOMSON, J. J.

Society of Arts.
Practical Measurement of Alternating Electric Currents, 447, 476, 505, 533 — FLEMING, J. A.

Société Internationale des Électriciens.
On the Light of the Electric Arc, 269 — VIOLLE, J.

Royal Institution.
Possible and Impossible Economies in the Utilisation of Energy, 362, 391, 414 — KENNEDY, A. B. W

Victoria Institute.
The Luminiferous Ether, 369 — STOKES, Sir G. G.

Municipal and Local Electric Lighting, &c.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 781.—Vol. XXXI. FRIDAY, MAY 5, 1893. PRICE FOURPENCE.
Annual Subscription (U.K.), 19/6

NOTES.

The elaborate Paper by Mr. Albion Snell on "The Distribution of Power by Alternate-Current Motors" has led to so good a discussion that we have given a rather more full report than usual. The remarks of most of the speakers were restricted, for a wonder, to the ostensible subject of the Paper, and did not wander off into details of motors. The very sensible views expressed by Mr. Mordey and others were confirmed by Mr. A. Siemens. *Drehstrom* motors and other more or less complicated expedients are, however, worth examining, and it is fortunate, perhaps, that those who, like Mr. Snell, have studied them, and others, like Mr. Brown, who have experimented with them, should so freely publish information on the subject. We have been blamed for a lack of enthusiasm about the *drehstrom* system, though we have always admitted that it may prove to be very useful in certain simple cases of transmission; as it is, the strict subject of Mr. Snell's Paper, the *distribution* of power by alternate-current motors, seems as far off as ever.

Uses for electric motors are being gradually developed, but as yet the filling up of the load curve of supply stations can hardly be said to have begun. Among applications which may be said to be in an experimental stage are a refrigerating ammonia plant and an electro-hydraulic lift in Victoria-street, Westminster. The former has been running for some time, and though the work is of a continuous character, suitable indeed for a synchronous alternating motor, it is said to be less costly than a gas engine. The lift is somewhat complicated; a motor drives a three-throw pump; this fills a hydraulic accumulator, and this works two lifts; the accumulator stops and starts the motor. For such work as this alternate currents would seem to be ill adapted.

Mr. Rimington has contributed a number of interesting experiments on vacuum tubes to the already large and rather heterogeneous stock which has been accumulating since the days of Gassiot. We have reproduced one or two of the diagrams from his Paper in our report of the last meeting of the Physical Society. Purely electromagnetic discharges, if we may be allowed to employ so loose a term, seem to be more amenable to scientific treatment than the luminous effects produced by electrostatic conditions. Where these two things are mixed, it is very difficult to follow the actions. The use of tinfoil caps seems to introduce a series of phenomena very different from the simple luminous ring discharges which attracted so much attention when shown before the Physical Society by Prof. J. J. Thomson. We understand that Dr. J. T. Bottomley has found that when such caps are used and are connected to earth, the effects are largely connected with the condition of the tubes—*e.g.*, as to exhaustion—and if the tubes are kept on the pump and not sealed off, differences in the vacuum, and even in the dryness of the outside, and a multitude of small particulars not easy to recognise, will give rise to a corresponding multitude of phenomena very different from those which may at first sight appear to be normal. It is difficult enough to apply mathematical treatment to oscillatory discharges under fairly simple conditions, but it seems very doubtful whether Mr. Rimington's algebra holds good inside tubes in which apparently unclosed circuits are formed in partial vacua. As soon as we get to vacua we find ourselves in a new world, where "bombardments," "Crookes' effects," and other occult varieties of the laws of Nature defy ordinary treatment; nor are we much wiser when we call an apparently electromagnetic luminosity a "discharge," and and an apparently electrostatic one "phosphorescence."

A copy of the official catalogue of the British Section of the Chicago Exhibition has been sent to us, and we congratulate the Royal Commission in adopting this sensible name instead of World's Fair Columbian Exposition. The only exhibits connected with English electrical engineering that call for any remark seem to be the engines by Galloways, Parsons, and Willans and Robinson, and a Siemens dynamo. These, no doubt, worthily represent what other English firms could send if they thought it worth while. An article written by Prof. Ayrton introduces the visitor to the ridiculous Electrical Section. The London Chamber of Commerce and the Institution of Electrical Engineers having failed to receive a single reply to the circulars which they were urged to send out, it is clear that it is by no accident that the English electrical trade does not care to employ this method of cultivating a foreign connection. By dint of repeating the names of the eleven electrical exhibitors, in most cases twice and in one case seven times, nearly four pages of the catalogue are filled with entries and cross references. Prof. S. P. Thompson contributes a chapter on "Instruments of Precision (other than Electrical and Magnetic)." These unfortunate instruments seem thus to be omitted altogether since Prof. Ayrton does not deal with them, but perhaps the Royal Commission did not consider that there was anything

Digitized by Google

to say about them, or thought that they were not in use in America. Prof. THOMPSON's chapter is, with others, introductory to "Liberal Arts." The only one of these which in any way concerns us is civil engineering; and this appears from the catalogue to be, if possible, more sorry a show than the Electrical Section. Besides these there is a "Machinery" Section which contains the names of four or five well-known firms and a number of the class who are only heard of at exhibitions.

THE withdrawal by the Corporation of the pecuniary support it has hitherto given to the City and Guilds of London Institute, a step adverted to in a somewhat oversolemn tone at the annual meeting of the Governors last week, is important rather as tending to lessen the prestige of the Institute than as placing it in financial straits. Since the commencement, the City Guilds and others have given £405,097. 4s. 6d. in support of the Institute connected with them. To this grand total the Corporation of the City of London has contributed £14,500 or rather less than 4 per cent. A contribution of this modest character is, we suppose, what is known as moral support.

THERE may be, and there are, two opinions as to the results likely to accrue from the present tendencies of the college training of engineers. Most of us agree, however, that little but good can come of the scientific training of those who may be called the non-commissioned officers of our industrial army. To those in daily contact with hard facts, a tincture of the science underlying their occupation is at once an intellectual relaxation and an addition to their utilitarian equipment. That being so, it is to be regretted that the Corporation has been obliged to forego the pleasure of forwarding so good a cause. Of course it may intend to apply the money elsewhere to a greater advantage, but of this, so far as we know, there is no suggestion.

THE manifest one-sidedness of the "Birkenhead" clause has been in a measure mitigated by the qualifying addendum introduced in a Provisional Order authorising the construction of a tramway system at Great Yarmouth. Traction and telephony will not be on an equal footing until protection is granted to telephone circuits only when they have been doubled and run with due regard to the prevention of ordinary every day induction. We print the clause in question in another column.

WITHOUT infringing the rules of the Institution of Civil Engineers as to publication of their proceedings, we may, perhaps, observe that the question of cycles, impulses, and direct driving, referred to by Mr. MCMULLEN in our Correspondence columns, was fully discussed after the reading of Mr. Dowson's Paper on January 10, 1893, although the particular case of alternators running in parallel was not considered. With reference to our correspondent's concluding suggestion, we are inclined to doubt whether any engines for electric supply, either gas or steam, should be run as low as half load, unless on exceptional occasions, and we are not aware that any success has attended attempts to vary the power of the explosions of gas engines. If alternators are run in parallel there should be no occasion for running on half load. Mr. SWINBURNE has pointed out that the use of governors, at all events separate governors, on the engines is disadvantageous in running alternators in parallel, and other engineers have rediscovered this fact. For non-parallel running, where the plant cannot be kept fairly well loaded by fidgeting with the switches, good governing is essential. One or two makers of gas engines seem to be fully alive to the necessity for continuous impulses. A gas engine is costly compared with a steam engine, and this is to some extent due to the idle strokes. If the impulses could be increased without the extra cost of hollow piston rods and additional cylinders, gas engines would, no doubt, be much more applicable to direct driving. But this is a mere truism, and is hardly a suggestion for which engine builders need be thankful.

MR. SIDNEY WALKER's long letter, which will be found in our Correspondence columns, begins with a few well-meant suggestions for the conduct of technical journals. Mr. WALKER seems to expect them to teach young or ignorant electrical engineers and electricians the common knowledge of their trade. Of all the ill-advised methods of imparting such knowledge, "articles in technical journals and Papers read before scientific societies" are, in our opinion, the worst. We occasionally provide articles for our younger readers dealing with elementary principles, and some time ago described the construction of a few simple instruments; these latter were to facilitate rough experimental work, not to teach instrument making. Mr. WALKER's favourite kind of technical journal would seem to be those wonderful publications which give their readers "Hints on making a handy howdah," "How to build a cathedral," "Notes on gilding wheelbarrows."

MR. WALKER suggests that oil paint and knotting "contain metallic bases which will be deposited by the leakage current," but does not say whether he has ever found a vestige of such deposition. His experience with insulated cables seems unfortunate; and believing, as we do, that fairly good qualities of insulation are not liable to the numerous defects of which Mr. WALKER complains, we can only conclude that in addressing himself only to "those who do not understand and who do bad work in consequence" he is at the same time discussing the use of bad materials.

WIDE as is the range of that group of sciences which is known as Physics, and notwithstanding its numerous practical applications, no purely scientific journal has yet been devoted to it. There are French and German periodical publications which form valuable records of research, and resemble in some respects our *Philosophical Magazine*. A periodical devoted to Physics does not appeal to a very wide circle of readers, and having but little commercial backbone, would probably fail to secure those pages of advertisements which are essential to the vitality of any urnal. A publication of this description is, nevertheless,

Digitized by Google

needed by physicists, and we have, therefore, great pleasure in announcing that Prof. E. L. NICHOLS and Prof. E. MERRITT, of the Cornell University, propose to start a fortnightly journal of experimental and theoretical Physics, to be called the *Physical Review*. We understand that the Cornell University will give the necessary financial support, and the names of its editors are sufficient to promise that the *Physical Review* will be a valuable addition to scientific literature.

No improvement can be reported as to Sir JAMES ANDERSON'S condition, which remains most critical.

Electric Railway Schemes for Berlin.—An electric railway scheme has been drawn up by Messrs. Siemens and Halske, and it is hoped that a concession will be shortly granted to this firm.

Royal Society.—The following Paper was down for reading before the Royal Society yesterday:—Profs. Reinold and Rücker, "On the Thickness and Electrical Resistance of Thin Liquid Films."

Cheap Telegrams.—In answer to a memorial from the Associated Chambers of Commerce, the Postmaster-General stated that, in the face of the deficiency in the telegraph revenue, he could not hold out any prospect of a further reduction of tariff.

Cable Interruptions.

	Date of interruption.
Para-Maranham	March 20th.
Paramaribo-Cayenne	April 15th.
Santiago de Cuba-Mole St. Nicholas	April 20th.
Gibraltar-Tangier	April 29th.

Electrical Bills in Parliament.—In the House of Commons on Monday last the Brighton and Rottingdean Seashore Electric Railway Bill was read a third time. On Tuesday the City and South London Railway Bill was read a third time, and the Barry Railway Bill was recommitted.

Antwerp.—The Antwerp Hydro-Electric Company, which, in carrying out the scheme of the late M. Van Rysselberghe of supplying high-pressure water to turbo-dynamos placed in sub-stations has to convey water at 30 atmospheres pressure, is using Mannesmann tubes for the purpose.

Steam Pipe Radiation.—According to results obtained at the physical laboratory of the Technical School of Chemnitz, the loss of heat by an iron pipe 4in. in external diameter, and conveying steam at 75lb. atmospheres pressure, is 1,530 kilogramme-calories per square metre per hour. This is equivalent to $2\frac{1}{3}$ H.P.

Personal.—M. Gaston Roux, the assistant editor of our esteemed French contemporary *L'Industrie Electrique*, and Chef des Travaux Pratiques d'Electricité à l'Ecole Municipale de Physique et de Chimie Industrielles, has been appointed consulting engineer to the Compagnie Française pour l'Exploitation des Brevets Thomson-Houston.

Telephone Wires.—The Corporation of Edinburgh, having objected to the right of the National Telephone Company to oppose their Improvements Bill, the question was considered by the Court of Referees. The Court has decided to give the Telephone Company a right to appear in order to claim compensation for any interference with their wires affixed to buildings of which they are not the owners.

Electrotechnics.—The glut of highly-trained electrotechnical men seems as depressing in France as elsewhere. M. Darras, in a recent number of *L'Industrie Electrique*, bewails the present state of the French electrical industry, which is, he says, a mere appanage of Switzerland and Germany, and asks if it is wise to go on turning out a product so little in request as "*ingénieurs d'une culture supérieure.*"

Edinburgh.—At the last meeting of the Town Council Bailie Walcot moved the disapproval of the minutes of the special meeting of April 21st, with reference to the city taking over the management of the electric light. There were in the Council, he said, 11 unrecorded votes. If these 11 supported him the majority of the Council would be in favour of his motion. After a discussion, lasting for an hour and three-quarters, a vote was taken, when the minutes were approved by 19 to 16.

The Telephone at Liverpool.—The largest telephone switch-room in the United Kingdom, and one of the largest in Europe, is that at Liverpool, where the National Telephone Company have just completed a new one. There are worked from the Liverpool centre 9,600 miles of wire, of which more than 7,000 are exchange and private wires. In 1882 the mileage of wires in Liverpool was only 463 miles; in February last it was 7,019. From the last published statistics it appears that the number of "calls" in the Liverpool centre is 42,800 per day.

Railway Telegrams.—On Tuesday last, on the consideration of the Great North of Scotland Railway Bill, a clause was inserted, on the motion of Mr. Arnold Morley, to provide that nothing in the Act should be deemed to impose upon the Postmaster-General the obligation of transmitting, under the provisions of the Telegraph Act, 1868, or any agreement between the Postmaster-General and the Company made in pursuance thereof, any larger number of telegraphic messages of the Company free of charge than he would have been bound to transmit had this Act not become law.

The Chicago Exhibition.—The American Society of Civil Engineers has addressed the following letter to the Secretary of the Institution of Electrical Engineers:—

DEAR SIR: In view of the probability that members of your Society will visit this city *en route* to the Columbian Exposition, the American Society of Civil Engineers has appointed Edward P. North, L. L. Buck, and Foster Crowell a Committee of Information and Courtesy at this house. This Committee will endeavour to furnish all engineers accredited by your Society with information as to rates, localities, and engineering works of interest. Please address such credentials and all correspondence on this subject to the Committee of Information and Courtesy, American Society of Civil Engineers, 127, East Twenty-third-street, New York City.

Overhead Wires at Middlesbrough.—At a recent meeting of the Streets Committee of the Middlesbrough Corporation consideration was given to an application to carry overhead wires from one hotel to another for the purpose of lighting both premises with electricity. The Mayor said he had discussed the subject with an electrical engineer, who informed him that the Corporation would do wrong if they gave permission to carry electric wires overhead. These overhead wires were a considerable danger, and "owing to the enormous current passing through them, they were in the habit of breaking"! It was decided to reply that the Corporation would not on any consideration allow overhead electric wires to be erected in the town.

Hanley.—At the quarterly meeting of the Town Council held on Tuesday last, the General Purposes Committee recommended that 30 1,200-c.p. arc lamps, instead of 20 of 2,000 c.p. each, be provided for the purpose of street lighting, principally in substitution for the large gas lamps, and that the electric light mains be laid for the purpose of the street lighting by incandescent lamps at the same time as the other mains, to replace the remaining gas lamps. The recommendations were confirmed. On the recommendation of the Electric Lighting Sub-Committee it was decided to advertise for an electrical engineer to have charge of the construction of the works, and the management of such works when completed, at a salary of £200 a year.

The Fellowship of the City and Guilds of London.—The Council of the City and Guilds of London Institute have elected Mr. H. A. Humphrey a Fellow of the Institute. This distinction is conferred upon those who, having matriculated and successfully completed the course of instruction prescribed for regular students at the Central Institution and obtained the diploma of Associate, shall have spent not less than five years in the practice of their profession, and shall produce evidence of having done some original and valuable research work, or of having otherwise contributed to the advancement of the industry in which they are engaged. Mr. Humphrey obtained the diploma of Associate in 1887, and is now engineering manager of the refined bicarbonate and crystal plant departments of Messrs. Brunner, Mond, and Co.

Cutting an Atlantic Cable.—In the House of Commons on Tuesday evening, Mr. H. Plunkett asked the Chief Secretary whether he was aware that the Atlantic Cable was cut near Ballycarbery, County Kerry, the week before last; whether he was aware that the tenant through whose land the cable ran demanded and received a sum of £20 before he would allow the Company's men to repair the cable; and whether, considering the great inconvenience caused to the public by such acts, he would take steps to see that their recurrence was prevented. Mr. J. Morley replied that the facts mentioned were substantially correct. It appeared that a sum of £25 was paid to the tenant on behalf of the Company in settlement of his claim. He (Mr. Morley) was not quite sure to what extent the Government had either power or duty in a matter of that kind, but it was now under consideration.

Water Power in Ireland.—The water power of the River Flesk, Killarney, has been used for over a century for working some flour and corn mills. Some time ago the proprietor, Mr. Chas. E. Leahy, applied for a Provisional Order for the lighting of the town of Killarney. A company was formed, and Mr. Victor A. H. M'Cowen was appointed to prepare plans, and carry out the work. The works are now almost completed, and houses are being wired. The current is transmitted from the generating station to a central switch station in the town (a distance of about a mile) at 2,000 volts. Three separate high-pressure circuits supply the town from the centre. Low-pressure mains fed from tranformers placed under the footway supply the consumers. The price charged is to be 6d. per unit. Since the Company has started, the price of gas has been reduced from 7s. 6d. per 1,000 to 5s. 9d.

The Bessbrook-Newry Electric Railway.—An accident of a serious nature occurred on the Bessbrook and Newry Electric Railway on Saturday last, about three o'clock. The car conveying passengers, to which were attached some waggon loads of linen and other goods, was proceeding from Bessbrook to Newry when one of the waggons by some means overturned and fell down the bank. A gang of men, with a lorry and the necessary breakdown appliances, proceeded to the scene of the accident, and at once commenced to clear the line. On the arrival of the electric car from Newry on the return journey, the lorry, which is lower than the electric car, was being pushed towards Bessbrook, when shortly after the start it got underneath the engine and car, throwing them off the rails, thus blocking the line again. The passengers in the cars received no injury whatever, and got out and walked to Bessbrook. The line, however, was blocked all the evening.

A Telephone Protection Clause.—Clause 10, Sub-section 1, of a Provisional Order, authorising the construction of a system of tramways in Great Yarmouth, runs as follows:—

The promotors shall so construct their electric circuits and other works of all descriptions, and shall so work their tramway in all respects as not injuriously to affect the working of any existing electrical circuits from time to time used or intended to be used for the purpose of telegraphic, telephonic or electric signalling communication, or the currents in such circuits, and shall use every reasonable means in the construction of their circuits and other works of all descriptions, and in the working of their undertaking, to prevent injurious affection, whether by induction or otherwise, to any electric circuits used or intended to be used for the purposes aforesaid (whether existing at the time of the construction of the electric circuits or other works of the promoters or not), or the currents in such circuits.—Provided that, as regards electric circuits erected or laid down by other parties than the promoters after the construction of the works of the promoters, this sub-section shall only apply if, in the erection, laying down and working of all such circuits, reasonable and proper precautions against injurious interference with other electric circuits have been taken, and if they have not been erected or laid down in unreasonably close proximity to the lines or works of the promoters.

Electrical Communication with Lightships. — In answer to a question put by Mr. E. H. Bayley the other night in the House of Commons, the Postmaster-General said that his department had no official knowledge of the circumstances attending the wreck of the "Enterkin," but it would appear that telegraphic communication with the Sunk Lightship would not have been of any avail to prevent the sad loss of life which then took place. The wreck appeared to have taken place on the North Galloper Sands, which were at a great distance from the Sunk Lightship, and the signals of distress did not appear to have been noticed at that lightship. He reminded the hon. member, however, that the whole question of telegraphic communication with lightships had been referred to a Royal Commission, whose first report had been presented to Parliament. The hon. member would see, on reference to that report, that the immediate restoration of communication with the Sunk was not proposed, but that telegraphic communication with the Kentish Knock Lightship was recommended. The Kentish Knock was much nearer the scene of the wreck of the "Enterkin."

Obituary.—We regret to record the death at sea, from coast fever, on April 30th, of Captain C. Bulmer Morfee. He entered the Eastern Telegraph service in 1882 as third officer, and rose step by step until he was appointed to the command of the Eastern and South African Company's cable steamer "Great Northern" in 1889. The deceased, who was very popular both on board his ship and in the service, was only 35. He was buried at sea between Brass and Principe, on the West Coast of Africa. An additionally sad feature of the case is that at the time of his death his wife was on her way to join him at the ship's station at Cape Town.——We regret to have to announce the death of Mr. Walter T. Glover, of the well-known firm of Walter T. Glover and Co., electrical wire makers, Salford. Mr. Glover had been out of health for several years. He was one of the few men who had the boldness to think and to say that the much-abused Electric Lighting Act of 1882 did more good than harm, inasmuch as it prevented the perpetration of a lot of crude electrical engineering. Mr. Glover was one of the first to realise the necessity for accurate tables of the resistance and weight of electrical conductors; and his tables practically held the field until the introduction of the standard wire gauge. Mr. Glover at one time took a very active interest in local affairs.——The death is announced at the age of 55 of M. Frank Géraldy, vice-president of the Société pour la Transmission de la Force par l'Electricité.

The City and Guilds of London Institute and the Corporation.—At the ordinary general meeting of the Governors of the City and Guilds of London Institute, last week, Lord Selborne, in moving the adoption of the annual report presented by the Council, said the Institute was approaching the *maximum* of its capacity, so far as some of the classes were concerned. The total number of the day and evening classes was 1,912. In the Central Institution the students numbered 199. In the Finsbury College there had been an increase of students from 198 last year to 213. He reminded those present that this was the last year in which the Council proposed to continue the large and liberal system of grants to technological examinations, as far as the country districts were concerned. The Council would, however, continue its assistance to London. With regard to the withdrawal of the support which the Corporation had hitherto given to the operations of the Institute, it was not for him to say what reasons had influenced the Corporation, but the subject was to him a very painful one. The paragraph relating to this matter, from the report of the Council, was as follows:—"The Council regret to report that the Corporation of London have withdrawn their financial support from the Institute. It may be remembered that the transfer of the classes of the City School of Art to the Technical College, Finsbury, was effected at the instance of the Corporation, and within the last few years the Institute had been at some considerable expense in improving the efficiency of this department of the College by laying down plant for lighting the studios by electricity. Although the contribution from the Corporation to the funds of the Institute has for several years been uncertain, its withdrawal at the present time, when the Council were looking forward to further extend the College, is most inopportune. The Council cannot help expressing regret that, at a time when all other large municipal bodies are actively taking up the question of the provision of technical instruction in their towns, the Corporation of London should be the one to withdraw altogether their contribution towards this object." In conclusion, Lord Selborne pointed out that there was a decrease in the income of the Institute for the current year. Last year the income was £33,093, and the expenditure £31,267, showing, therefore, a balance of £1,826. The estimated income for the present year was, however, £31,810.

ELECTROMAGNETIC THEORY.—XLIX.

BY OLIVER HEAVISIDE.

(Continued from page 709, Vol. XXX.)

§ 198. We are now prepared to somewhat understand the nature of the changes suffered by electromagnetic waves in transit through a conducting medium. It being the distortion due to the conductance alone that is in question, we eliminate that due to other causes by choosing plane waves for examination, since these do not suffer any distortion in a homogeneous dielectric when it is non-conducting. Imagine, then, a simple electromagnetic plane wave-sheet of small depth to be running through a dielectric at the natural speed conditioned by its inductivity and permittivity. At any stage of its progress, let the medium become slightly electrically conducting all over, not merely in advance of the wave but behind it as well, for a reason that will presently appear. What happens to the wave now that the fresh influence is in operation?

A part of the answer we can give at once, by the previous. The wave-sheet will move on just as before, but will attenuate as it goes, according to the time-factor $\epsilon^{-kt/2c}$. Since we suppose the conductivity to be slight, it follows that a great distance may be traversed before there is notable attenuation. We also know that the total induction remains constant. The rest of it—that is, what is not in the sheet at any moment—is therefore left behind. The rejecting process commences the moment the conductivity is introduced, and continues to act until the plane wave is attenuated to nothing. The rejected portions travel backwards. But they are themselves subject to the same laws as the main plane wave, and so get mixed up. The result is that at time t after the introduction of the conductivity, the whole region of disturbance is spread over the distance $2vt$, half to the right and half to the left of the initial position. At the advancing right end we have a strong condensed disturbance, viz., the original wave attenuated, and behind it a weak diffused one. We can therefore, without misunderstanding refer to them as the head and the tail, without any body to complicate matters. Now the nature of the tail is quite different as regards the displacement and the induction. It is therefore convenient to regard one of them alone in the first place, and, of course, we select the induction, on account of the simple property of persistence that it possesses. We can distinguish three or four different stages in its development.

The first stage is when the attenuation of the head is not great, say, whilst the head decreases from 1 to 0·75. Whilst this occurs, the total induction in the tail rises from 0 to 0·25. The tail is long and thin, and tapers to a point at its extreme end, or tip, at distance $2vt$ behind the head, and is thickest where it joins on to the head.

The second stage roughly belongs to the period during which the head further attenuates from 0·75 to 0·5 or 0·4. The total induction in the tail then increases from 0·25 to 0·5 or 0·6. During this stage we find that the tail, which has, of course, greatly increased in length, does not go on increasing in thickness at the place where it is developed, but stops increasing and shows a maximum at or near that place.

The third stage occurs during the further attenuation of the head to, say, 0·1, whilst the total induction in the tail increases to 0·9. The maximum thickness of the tail is now a long way from the head, and at the end of the stage is nearer to the middle than to the head. Of course, since the head itself is now so small, the additions made to the tail must also become smaller.

The fourth stage is when the head practically disappears and all the induction is in the tail. The maximum thickness is now nearly in the middle—on the right side, however—and the tail is nearly symmetrical with respect to its middle, where there is a swelling, beyond which the tail tapers off both ways to its two tips.

The final state is the consummation of the previous, and is one of perfect symmetry with respect to the middle of the tail, which is situated exactly where the plane wave was when the spreading began. The spreading now takes place according to the pure diffusion law, as of heat by conduction.

Now as regards the displacement in the head and tail in the different stages. In the first and second stages the displacement is wholly negative in the tail, assuming it to be positive in the head, where, it should be remembered, it attenuates in the same manner as the induction which accompanies it. Thus, when the head has fallen to 0·9, the total displacement in the head and tail has fallen to $(0·9)^2$ or 0·81, so that the total negative displacement in the tail is of amount 0·09, which is not much less than the coincident induction. And when the head has attenuated to 0·8, and the total displacement to $(0·8)^2$ or 0·64, the negative displacement in the tail amounts to 0·16. But, unlike the induction, the displacement increases in the tail from the head up to not far from the tip, where, of course, it falls to zero. There is no tip at the forward end. But as the tail stretches out further to the left, and has fresh additions made to it on the right side, the decrease of the density of displacement in passing towards the head continues, until somewhere about the end of the second stage, it becomes zero next the head. This node is approximately at the place where the induction has its maximum. When the head has fallen to 0·4, we have the total displacement attenuated to 0·16, so that the negative displacement in the tail amounts to 0·24.

In the third stage the displacement is negative from the tip up to somewhere near and beyond the maximum of induction, and increasingly positive in the remainder, up to the head. That is, the region of positive displacement now extends itself from the head a good way into the tail. At the same time the place of maximum negative displacement moves forward.

During the fourth stage, the place of maximum negative displacement shifts itself to nearly the middle of the region between the tip and the node, beyond which the positive displacement has a nearly similar distribution, with a maximum. But this positive distribution is only three-parts formed, as the head is still of some importance. The fifth stage completes the formation of the tail, with the displacement negative in one half and positive in the other, and nearly symmetrical with respect to the middle. Finally, we come to a state of perfect symmetry, with one maximum of induction and two (or a maximum and a minimum) of displacement. This may be readily understood by considering that in the expression for the true electric current, $k\mathbf{E}+c\dot{\mathbf{E}}$, the second term finally becomes a small fraction of the first, or the current is practically the conduction-current only. Then $\mathbf{E}$, and therefore the displacement, is proportional to the space-variation of the induction. Owing to the tail being made up of a complicated mixture of infinitesimal electromagnetic waves going both ways, we lose sight of the fundamental property of elastic wave-propagation in a dielectric, the resultant effect being propagation by diffusion now, or very nearly so. The approximation to this result is closest in the middle of the tail. At the tips, on the other hand, we still have elastic waves, but, of course, of insensible strength.

Now, suppose that the initial state is one of induction only, though still in a plane sheet. It may be regarded as the coincidence of two plane electromagnetic sheets of half the strength, with similar inductions and opposite displacements. The subsequent history may, therefore, be deduced from the preceding. The initial induction splits into two halves, of which one moves to the right at speed v, and the other to the left. The history of the first wave as distorted by the conductance has been given. That of the second wave is the same, if we allow for the changed direction of motion and sense of the displacement. So we have only to superpose the two systems to show how an initial distribution of induction in a plane sheet splits and spreads, and the accompanying electric displacement. We have two equal heads, separating from one another at speed $2v$, whilst the two tails unite to make a stouter kind of tail (referring to the induction) joining the two heads. This tail is always thickest in the middle. In fact, the distributions of induction and displacement are symmetrical with respect to the initial position from the first moment. In the final state that is tended to, when the tails have vanished, the induction is distributed in the same way as in the former case, in spite of the remarkable difference in the initial phenomena.

If, again, the initial state is one of displacement alone in a plane sheet, this generates two oppositely-travelling electro-

Digitized by Google

magnetic waves in which the displacements are similar and the inductions are opposite. The result is therefore to be got by combining the previous solution for a wave of positive induction and displacement moving to the right, with a similar wave of negative induction and positive displacement moving to the left.

Whatever be the magnitude of the conductivity, if finite, the same phenomena occur during the conversion of elastic waves to diffusion waves, and they may be represented by the same diagrams, if suitably altered in the relative scale of ordinates and abscissæ. But by increasing the conductivity from the small value which makes the above-described process take place over a considerable interval of time, we make it occur in a small interval only; and when we come to what are usually considered good conductors, viz., metals, then the interval of time is so small that we may say practically that the heads vanish almost at once, and before the propagation has proceeded any notable distance. The rest of the story is the spreading by diffusion or mixture. Thus we have an important practical distinction between the very good and the very bad conductor, as regards the manner of propagation of induction. In the former the electric displacement is of no account hardly, except perhaps for very short waves, and the practical theory is the theory of diffusion. At the other extreme are perfect non-conductors, in which the propagation is entirely by elastic waves. Between the two we have, in bad conductors, a mixture of the two kinds, though with a continuous transition from one kind to the other. The mathematical treatment of elastic waves is the easiest. The next in order of difficulty are the waves of pure diffusion, by the ordinary Fourier mathematics. The most troublesome are the intermediate forms of changing type, and the full analytical results are best got by a generalised calculus. But the general nature of the results may be obtained approximately by easy numerical calculations, with diagrammatical assistance. This is explainable without difficulty, and may be entered upon later on, when we come to detailed problems.

In the above the conductivity has been electric only, and we have seen that there is a great difference between its effects on the electric and on the magnetic flux, which arises from the positive reflection and persistence of the latter, and the negative reflection and subsidence of the former flux. The corresponding effects in a magnetic conductor may be readily deduced by the proper transformations, and exhibit analogous differences. Thus, starting with a pure plane wave sheet moving to the right, it is now the displacement that is conserved and divided between the head and tail, being initially all in the head, and finally all in the tail. On the other hand, the induction is negative in the tail at first and until the attenuation of the head is considerable. After this, the region of positive induction extends from the head into the tail. As time goes on, and the head disappears, we have negative induction in one half and positive in the other (forward) half, whilst the displacement is positive all along it, with its maximum nearly in the middle. In the final state of diffusion we have symmetry with respect to the initial position of the wave, and the induction is proportional to the space-variation of the displacement. The second term of the magnetic current $g\mathbf{H}+\mu\dot{\mathbf{H}}$ is then a small fraction of the first term.

Now, in the medium with duplex conductivity we must take the distortionless condition for the standard state. When this obtains there is no tailing, although the head (displacement and induction together) attenuates according to the time-factor $\epsilon^{-kt/c}$. But if the electric conductivity be in excess (that is, greater than is required to make $k/c=g/\mu$) there is tailing of the kind described as due to electric conductivity, with the induction positive and the displacement negative in the tail at first. And if the magnetic conductivity is in excess, the tailing is of the other kind, with positive displacement and negative induction at first. But of course the details are not the same, because both the fluxes now attenuate to zero in time, in the tail as well as in the head.

§ 199. We must now endeavour to give a general idea of the tailing of waves when they run along conducting wires, in co-ordination with the previous. In the first place, observe that although the lines of electric and magnetic force in a pure electromagnetic sheet in ether must be always perpendicular to one another, yet they need not be straight lines, except in their elementary parts. On the contrary, we may have an infinite variety of distributions of the electric and magnetic fluxes in curved lines in sheets which shall behave as electromagnetic waves. Keeping to plane sheets, we may take any distribution of displacement in a sheet that we please, and make it an electromagnetic wave by introducing the appropriate distribution of induction, also in the sheet. If left to itself it will move through the ether one way or the other at speed v, according to the directions of the fluxes. It should be noted, however, that the fluxes should have circuital distributions. For if not, and there is electrification or its magnetic analogue, they, too, should be moved through the ether so as to exactly keep up with the wave. If the electrification does not move thus, we have a changed state of things. But there is a way out of this difficulty. Let the displacement, when it is discontinuous, terminate upon infinitely-conducting lines, or surfaces of cylinders, according to circumstances. The interference produced by holding back the electrification will then be done away with. It is sufficient for explicitness to take a single definite case.

Let the displacement in a plane electromagnetic sheet terminate perpendicularly upon a pair of perfectly-conducting cylindrical tubes placed parallel to one another. One is for the positive and the other for the negative electrification. The induction will then go between and round the tubes. One tube may enclose the other, but, preferably, we shall suppose this is not the case, so that our arrangement resembles a pair of parallel wires. Now the wave will run through the ether in the normal manner, without distortion or change of type, and will carry the electrification (on the conductors) along with it.

Similarly if the tubes be magnetic conductors, if the induction terminates perpendicularly upon them, whilst the displacement goes between and round them. So far, then, the theory of the propagation of the wave is unaltered.

But this property may be greatly extended. The medium outside the tubes through which the wave is moving may be made electrically conducting. The theory is then identical with that of § 198, as regards the distortion produced and the gradual destruction of the wave, ending in the process of diffusion. This will be true whether the tubes are perfect electric or magnetic conductors, provided we have the displacement terminating upon them in the first case and the induction in the second.

Again, if the medium is magnetically conductive, the theory still holds good, with the same reservations as regards terminating the fluxes. But now the distortion is of the other kind, with persistence of the displacement and subsidence of the induction.

Finally, the theory is still true when the medium is a duplex conductor, whilst the tubes are either perfect electric or magnetic conductors, according to choice. The distortion is now of the electric or of the magnetic kind, according as k/c is greater or less than g/μ.

But not one of these cases is quite what we want to represent propagation along real wires. The nearest approach is the case of finite electric conductivity in the medium combined with perfect electric conductance of the tubes. If we make their conductance be imperfect, we then come close to the real problem. Now when we do this, the theory, when done precisely, becomes excessively difficult, for two reasons. First, the waves in the ether outside the tubes are no longer plane; and next, the penetration of the disturbances into the substance of the tubes in time by means of cylindrical waves has to be allowed for. The latter is, of course, more necessary when solid wires are in question. A practical working theory is seemingly impossible of attainment by strictly adhering to the actual conditions. But one is possible by taking advantage of the fact that the waves in the ether are very nearly plane under ordinary circumstances. Of this we may assure ourselves by considering that the tangential component of the electric force at the surface of a wire (upon which the penetration depends) is usually a very small fraction of the normal com-

Digitized by Google

ponent of the same outside it. The practical course, then, is to treat the waves in the dielectric as if they were quite plane. This does not prevent our allowing for the distorting effect of the resistance of the wires. It has the effect of making our solutions approximate instead of complete. But the important thing is to have a theory that, whilst sufficiently accurate, is practically workable, and harmonises with more rudimentary theories. This is precisely what we do get, as done by me in 1886. The theory is brought to such a form that we may employ it in several ways, according as circumstances allow us to ignore this or that influence. We may, for example, treat the wires as mere resistances (constant), and this is quite sufficient in a variety of applications. Or, using the same equations with more general meanings attached to the symbols, we may find the effects due to the imperfect penetration of the magnetic induction and electric current into the wires when subjected to varying forces at their boundaries, either simple harmonically or otherwise. Furthermore, the theory is in such a form that it admits readily and without change of the introduction of terminal or intermediate conditions of the kind that occur in practice, whose effects are brought in according to the usual equations of voltage and current in arrangements of apparatus.

What we are immediately concerned with here, however, is the connection between this theory and the general theory of waves in a medium of duplex conductivity. When the tubes are so thin that penetration is practically instantaneous (for the wave-length concerned), a constant ratio is fixed (assisted by Ohm's law) between the intensities of magnetic and of tangential electric force at the boundary of the tube, where it meets the dielectric. And when we incorporate this result in the second circuital law applied to any section of the circuit formed by the parallel tubes, we find that the result is to turn it to the form expressing the existence of magnetic conductivity in the outer medium, without resistance in the wires. That is, the resistance of the wires has the same effect in distorting and dissipating the waves outside as the fictitious magnetic conductivity in the medium generally. This is true in the first and most important approximation to the complete theory. It is a point that is not altogether easy to understand, because the magnetic conductivity is fictitious, whereas the resistance is real. This, however, may be noted, that the theory of propagation of plane waves in a medium of duplex conductivity bounded by perfect conductors for slipping purposes, professes to be a precise theory, whereas the other, although concerning the same problem in most respects, professes to be only approximate so far as the influence of the wires is concerned.

(To be continued.)

SOME APPLICATIONS OF ELECTRICITY TO CHEMISTRY.*—III.

BY JAMES SWINBURNE.

The next division of my subject is the electrolysis of gas. The study is new, and even the expression "electrolysis of gas" is unfamiliar; nevertheless, according to the most recent researches, gases are, to all intents and purposes, electrolysed by the electric discharge. It has been known for a long time, however, that oxygen can be converted into a peculiar modification, namely, ozone, by the electric discharge. This substance is of great value as an oxidising agent for use in bleaching and disinfecting. Ozone is now made industrially. An alternating-current dynamo is employed, and the pressure is raised from 10,000 to 30,000 volts, this pressure being applied in an ozoniser. The various ozonisers in use are much the same in principle. If two electrodes were placed close together in, say, oxygen or air, there would be no electrical discharge to speak of until they were brought so close that a disruptive discharge took place. An arc would then be formed, and this is not what is wanted. What is required is some arrangement by which the air can be broken down. If a piece of glass is placed between the electrodes, air may be broken down, and the glass will support the dielectric stress itself so that there is no arc. As the pressure rises from zero the electric displacement in the air and glass increases until stress in the air causes that part of the circuit to break down. The glass then for the moment bears nearly the whole pressure. As glass has a very high specific inductive capacity, it allows a very large electrical displacement in proportion to its thickness and to the pressure applied; it therefore allows a considerable discharge through the air. Immediately the discharge has taken place the air recovers itself, so that there is little or no stress on the air, nearly the whole being on the glass. As the pressure rises more stress is put on the air and on the glass, and the air breaks down again, and so on, until the top of the alternating wave of pressure is reached. As the pressure falls, the glass, being under stress, communicates its stress to the air again and breaks it down in the reverse direction, and so on until the zero of the electric pressure is reached. The alternating pressure thus produces a series of electric discharges, which have here been explained according to the more recent methods of regarding the action of electric stress on dielectrics. In older language it would have been said that the electricity was charged on to the surface of the glass. So far we have spoken of a series of disruptive currents across the air space. Much of this is really oscillatory, so that in the ozoniser there is really an irregular alternating current of very high frequency. In fact, most of the well-known frequency experiments can be shown by means of a glass plate and a high-pressure transformer.

Practically the ozoniser has two plates of glass, the disruptive discharge taking place between them, the electrodes being on the outside. By this means the contact of the ozone with the metals is avoided. The simplest form of ozoniser consists of an inner and outer tube, with one electrode inside the inner tube and the other outside the outer. The air or oxygen to be treated is passed through the annular space between the tubes.

So far we have been considering electrical currents only, and little has been said about electrical energy or electrical power. In electrolysis of water, for example, we have said nothing about the work done in decomposing, say, a pound of water into oxygen and hydrogen. As the quantity of electricity used varies as the quantity of water decomposed, the other factor, the pressure necessary to cause the decomposition, must remain constant, and must be independent of the rate at which the electricity is passed, that is to say, of the current. Of course, there is extra pressure needed to overcome the resistance of the cell and connections, but that is lost; it is not converted into chemical work. The electromotive force necessary to produce electrolysis is of vital importance in commercial work. It is not necessarily proportional to the heat of combination of the radicles set free. This common error cannot be too often exposed.

Electrical power can be used in another way, namely, by locally heating a conductor to a very high temperature. The white-hot filament of an electric lamp is a good example. In its preparation it is heated electrically in contact with a hydrocarbon. This is decomposed, and carbon is deposited on the filament, which is then said to be "flashed" or "treated." The crater of the arc shows the highest temperature attainable with carbon electrodes. It has been pointed out by Prof. Silvanus Thompson that the crater rises to the temperature of volatilisation of carbon, and no farther; but the volatilising point of carbon is a very good temperature to reach. The uniformity of the temperature of the arc permits of an application of electricity to optics; in fact, it gives a standard of light. Prof. Thompson and the lecturer suggested this simultaneously, and the lecturer designed a screen standard. This has now been carried out practically by M. Blondel, and an account has been presented to the French Academy. Mr. Trotter and Prof. Thompson are also engaged on elaborate researches on the same subject.

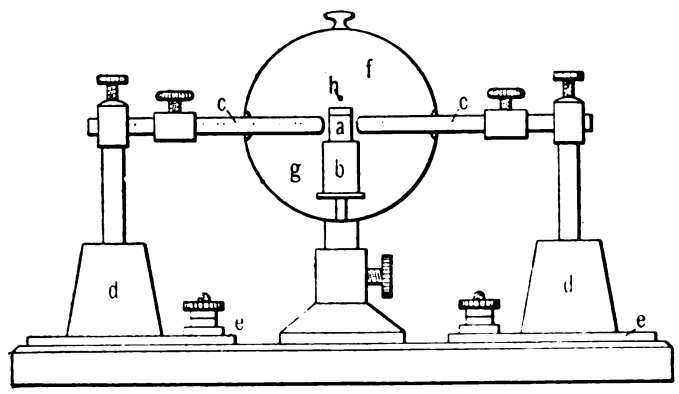
The electrical furnace, like many other electrical inventions which are supposed to be quite new, was used by Sir Humphrey Davy nearly a century ago, and somewhat later by Staite,

* A course of three "Tyndall" lectures at the Royal Institution.

Digitized by Google

who used the arc furnace for obtaining fused iridium from its oxide for making incandescent lamps.

There are two varieties of the electrical furnace. The oldest is the arc form. A carbon crucible is used, and the arc is allowed to play on the inside from a carbon electrode. This form can hardly be employed on a large scale, but is convenient for laboratory work. The only commercial form is the Cowles, or incandescent electrical furnace. This furnace consists of a mass of carbon, with which the oxide to be reduced is mingled, and a pair of large carbon electrodes. The charge is rendered incandescent by the passage of an enormous current, and when it reaches a certain temperature the oxide is reduced by the carbon. This furnace is used for reducing alumina. The aluminium is difficult to collect, and there is a large demand for aluminium bronze and aluminium iron, so these alloys are manufactured. Mr. Cowles also used his furnace for the reduction of silicon, chromium, boron, and other elements which are with difficulty reduced from their oxides. Mr. Cowles informed the lecturer some years ago that he found his furnace would reduce all the refractory oxides, but aluminium was the only product he considered of commercial value. Quite recently M. Moissan has reduced various refractory oxides by means of the Staite furnace, but it is only fair to Mr. Cowles to state that these results are quite old. This is not the case, however, with M. Moissan's most brilliant achievement, the production of black diamonds. To produce these a mass of iron is heated to a very high temperature by the arc furnace in contact with carbon.



Arc or Incandescent Crucible Furnace.

(*a*.) Carbon Crucible with Carbon Lid. (*b*.) Block of Carbon to support Crucible. (*c c*) Carbon Electrodes. (*d d*) Stands for Electrodes, made to slide on Brass Plates *e e*, so that the Carbons can be easily adjusted without being disturbed by imperfectly Flexible Connections. (*f g*.) Top and Bottom Halves of Containing Sphere. (*h*.) Pinhole for Projecting Image of Crucible on Screen, so that it can be watched.

It absorbs a percentage of carbon. It is then cooled suddenly, and the contraction of the outside of the mass causes enormous pressure in the interior. The carbon which crystallises out in the centre is said to crystallise in the octahedral form, and, in fact, to be black diamond. The Cowles furnace is now used largely for the production of phosphorus from calcium phosphate, by a process invented by Messrs. Readman and Parker.

For experimental purposes the lecturer has devised an arc furnace in which the materials to be operated are not acted upon by the arc directly. A small carbon crucible with a carbon lid holds the material to be treated. It is placed between the tips of two electrodes. The current is started and the electrodes are moved apart so as to allow two arcs to play on the little crucible. This furnace will reduce uranium oxide, alumina, and other refractory oxides. If the electrodes are kept in contact with the crucible an incandescent furnace is obtained. The great advantage of this furnace is that it is easy to control, and that the charge does not get mixed with lime and cannot run away into cooler places in the furnace. The whole is held in a lime body. In another form, shown in the accompanying illustration, the crucible is at the centre of two copper hemispheres, silvered and polished inside. A pinhole in the side allows the image of the hot crucible to be projected on a screen.

[Experiments were made showing the softening point of carbon, the decomposition of hydrocarbon gases and liquids, the production and properties of ozone, and various sorts of electrical furnace were shown. The fusion of platinum, chromium, tungsten, and lime, and the reduction of uranium and other refractory oxides were shown.]

THE "GENERAL" METER.

The principle of the "General" meter resembles that of the well-known Aron meter in that two pendulums are employed, one vibrating under the action of gravity alone, and the other being accelerated or retarded by a magnetic field. But it differs in two important points from differential meters of the Aron type, for the maintaining force does not depend on a wound-up spring, and the recording train is not driven by an escapement. The pendulums are in fact simply swinging bars, kept in motion, only so long as any current is passing through the main coils, by a gravity impulse lever, and this gravity piece is lifted by a shunt magnet, and at the proper moment is allowed to fall against the pendulum (the arrangement being duplicated) The same magnet, in lifting the gravity piece for another impulse, drives the differential counting trains. The function of the pendulums is simply to make and break contacts. The coils of the electromagnets which are employed to lift the impulse weight are joined up with suitable high-

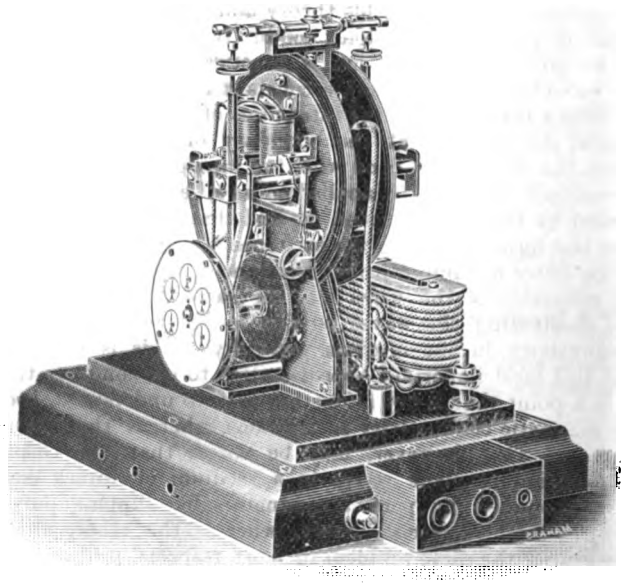


FIG. 1.—The "General" Meter.

resistance coils, and are connected in shunt across the supply mains. The total resistance of these coils of each clock being 6,000 ohms, the current necessary to drive each clock is only one-sixtieth of an ampere, and as this is only required during less than one-half of the swing, and during the time only while the light is used, the cost of driving need not be considered. By a special arrangement of the winding of these coils, sparking at the contacts is suppressed.

The current to be measured passes through a solenoid of special shape, the resistance of which is extremely low, placed immediately below the magnet-bar, and which it influences as stated before. The lower pole of the solenoid acts upon a light pivoted magnetic needle, so that directly a current passes through the turns of the solenoid the needle is deflected, and by that means the contact is made which closes the circuit of the electromagnet coils, and both clocks immediately start working. A current considerably less than required for one lamp is sufficient to deflect the needle and to start the clocks, which cease to register when the current is switched off.

The same electromagnets which lift the gravity impulse weight also actuate the recording apparatus. The axle of one clock being hollow allows the axle of the other clock to be brought through it. The hollow axle carries a frame and dial which revolve together, and the other axle carries the wheel which gears into one in the frame, so that if the two axles revolve at exactly the same rate, a pointer fixed to the wheel carried by the frame does not move from its position. When, however, one axle is moving faster than the other, the difference is indicated by a motion of the pointer, and it is evident that by suitable arrangements of counting gear the registration of the difference in the number of revolutions made by the axle in any given time is easily and simply effected. The terminals,

Digitized by Google

which are outside the meter, are protected by a cover, which the fitter can remove when connecting up, and after he has replaced it this can also be sealed. In order to protect the pendulum from injury during transport a clamping arrangement is provided, which can be manipulated without removing the cover.

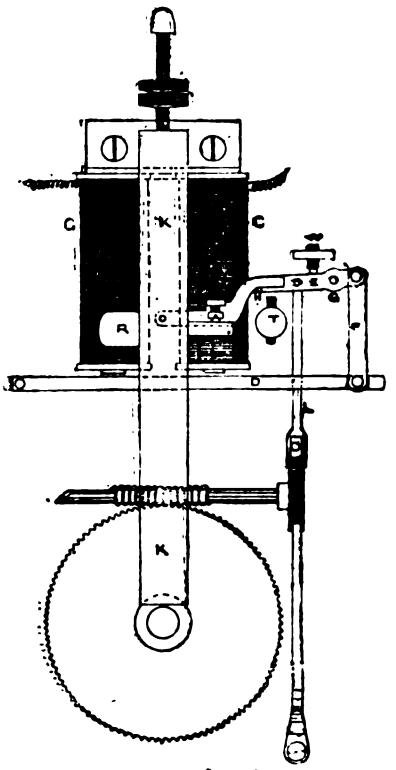

FIG. 2.—Gravity Impulse Gear.

A general view of the meter with the cover removed is given in Fig. 1. The impulse gear is shown in Fig. 2, and Fig. 3 is a sketch of the connections (diagrammatic) of the whole meter. When a current passes through the main coils, consequent upon the

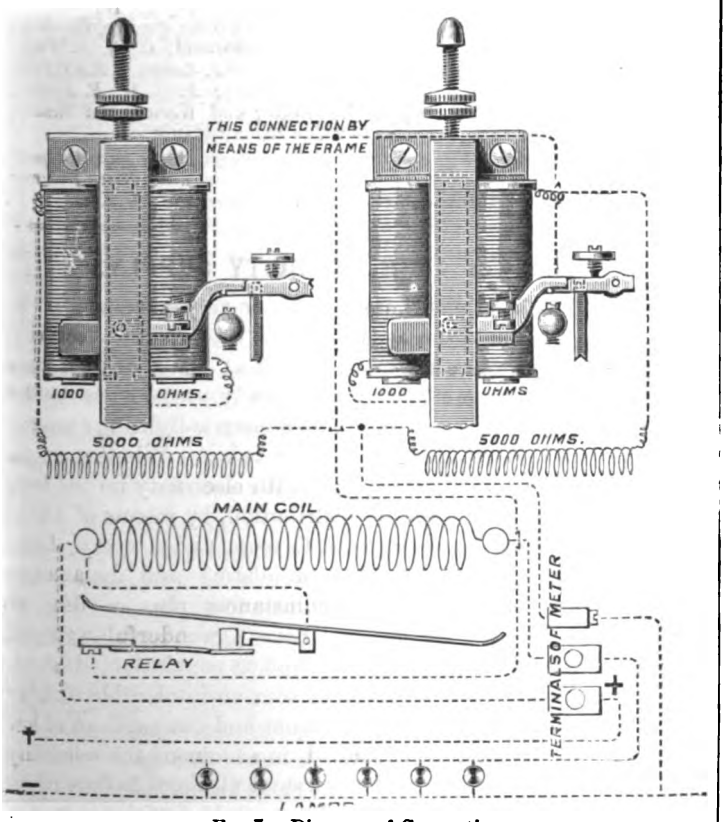

FIG. 3.—Diagram of Connections.

switching on the lamps, the magnetic relay needle is deflected, closing the contacts and putting the contact screws in connection with the shunt circuit for driving the clocks. As both clocks are electrically joined up alike it will only be necessary to follow from one of these screws the course of the current. The pendulum bar K (Fig 2) is insulated from the frame and connected to one end of the coil C, the other end of the coil being connected through a suitable resistance to the return lead, so that the pendulum cross-piece R being in contact with the contact screw S, the coils are energised, the armature D is raised, and the lifting pin H on the end of the lever E is, therefore, depressed. The full weight of the gravity piece then acts upon the bar K through the cross-piece R, starting it into vibration. When the end of the gravity piece strikes the stop T, the bar continuing its forward swing breaks contact between screws S and cross-piece R. The armature D immediately falls, and acting on the lever E through the link G makes the lifting pin H raise the gravity piece, the position to which it is lifted being determined by the stop screw W.

When the bar swings back the circuit is again completed through contact of screw S with cross-piece R, and the cycle of operation is regularly repeated during the time the magnetic relay needle is deflected by the current passing through the main coil. The impulse necessary to maintain the vibrations of the bar K is obtained from the falling of the gravity piece from the definite position of the lifting pin H to that of the stop screw T, and is independent of variation within a wide range of the driving current, due to fluctuations of voltage on the supply mains. Besides lifting the gravity piece, the armature also actuates the pawl or pullet connected with the registering gear, as indicated in the sketch, so that for every complete swing of the pendulum bar a tooth in the wheel is moved forwards, and that swing registered.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, May 5th.

CHEMICAL SOCIETY.

8 p.m. Hofmann Memorial Meeting: Addresses by Lord Playfair, F.R.S., Sir F. A. Abel, F.R.S., and Dr. W. H. Perkin, F.R.S.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Fogs, Clouds, and Lightning," by Shelford Bidwell, F.R.S.

MONDAY, May 8th.

ROYAL INSTITUTION.

5 p.m. General Monthly Meeting.

TUESDAY, May 9th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting: Paper to be further discussed:—"Mining and Ore-Treatment at Broken Hill, New South Wales." By M. B. Jamieson, Assoc. M. Inst. C.E., and John Howell.

WEDNESDAY, May 10th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Paper to be read: "The Richmond Lock and Tidal Weir," by J. B. Hilditch.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Students' Meeting. Paper to be read: "The Introduction of Rubble Blocks into Concrete Structures," by J. Wilson Steven, Stud. Inst. C.E.

ROYAL SOCIETY.

9 p.m. Conversazione.

THURSDAY, May 11th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "The Atmosphere," by Prof. Dewar, F.R.S.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting. Paper to be read: "On the Prevention of Sparking, Compound Dynamos without Series Coils or Magnets, and Self-Exciting Dynamos and Motors without winding upon Field Magnets," by W. B. Sayers, Assoc. Inst. E.E.

FRIDAY, May 12th.

PHYSICAL SOCIETY.

5 p.m. Papers to be read: (1) "The Drawing of Curves from their Curvature," by C. V. Boys, F.R.S. (2) "The Foundations of Dynamics," by Dr. Oliver Lodge, F.R.S.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Isoperimetrical Problems," by Lord Kelvin, P.R.S.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

Other Countries	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 4.30 p.m. Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.*

"THE ELECTRICIAN" SERIES *at present consists of—*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.

VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free.

VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post-free.

The same in German, price 8s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING (1893). By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

SPECIAL NOTICE.

With the current Number of "THE ELECTRICIAN" is issued (Gratis) the Index to Vol. XXX. Complaints of non-receipt should be at once forwarded to the Publisher.

NOW READY.

Volume XXX. of "THE ELECTRICIAN," price 12/6; post free, 13/6; abroad carriage extra.

NOW READY.

Cases for binding Volume XXX., price 2/0, post free, 2/3.

The Publisher is able to supply a set of the Volumes of "THE ELECTRICIAN" complete except for three Nos. Price on application.

STEEL-PLATE PORTRAITS

Of Willoughby Smith; W. H. Preece, F.R.S. (President of the Institution of Electrical Engineers); Michael Faraday; Sir John Pender, G.C.M.G., M.P.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Patey, C.B.; Dr. John Hopkinson, F.R.S.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz; Prof. W. E. Ayrton; Lord Rayleigh, F.R.S.; Cyrus W. Field; and Werner von Siemens, have been issued as Supplements to "THE ELECTRICIAN."

Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price 4s. 6d., carriage paid (U.K.).

VARIETY IN ELECTRICITY SUPPLY.

Variety, we are somewhere told, is the very spice of life. If that be so the humdrum aspect of the business of electricity supply must be more apparent than real. We do not here refer so much to multiformity of supply systems as to the widely diverse conditions under which electric-lighting concerns are promoted, started and have their being. Whether or no a certain locality shall be supplied with electricity on the two, three or five wire system of distribution, by means of transformers in every house, or transformers under every street-crossing, or by an array of accumulators and dynamotors depends on topographical circumstances plus a dose of prejudice. Sleepy Hollow may have a wonderful waterfall three miles from the parish church, and its population, although extremely select, may be sprinkled over an intolerable number of acres; yet if fate decree that an out-and-out partisan of low pressure supply shall be consulted, in a moment the reliability of the waterfall is impugned and a stout girdle of feeders is put round the place in less than the proverbial eighty minutes. The high-pressure man does much the same when opportunity offers; the most compact little area imaginable cannot induce him to forego his high volts or his 100 ∽. But, as we have already hinted, we do not feel called upon to investigate the

Digitized by Google

extremely thorny law which leads so many electrical engineers to invariably recommend exactly the same specific, be the circumstances of each case what they may. On the contrary, feeling conscious of the existence of a strong "insular prejudice" in favour of English ways of going to work, we hope to modify the same by a glance at one or two peculiarities of the electricity-supply business abroad.

In the first place, across the Channel we have the baneful "concession" method of procedure in full force. A monopoly, more or less complete, is granted for a certain term of years, generally too short to attract any but speculative capitalists into the field, in return for a small sum down and a multitude of petty, indirect municipal pickings—the more numerous, the more petty; the more indirect, the more they commend themselves to the parochial mind—the net *quid pro quo* being a permit to freely squeeze the public. With an annual tax upon every yard of main, an obligation to light the streets for less than, and the public buildings for little more than, cost price and various other burdens of a similar nature, small wonder if the Société Anonyme d'Éclairage Électrique cannot manage to sell the hectowatt-hour at a reasonable price to non-municipal customers. There is a marked tendency amongst our own local authorities to convert the powers conferred upon them by the Electric Lighting Acts into a concession-mongering apparatus. It would be well if the municipal electors would insist upon electric lighting being either thoroughly municipalised, as has been done so successfully in Switzerland, or given a free hand. With the Electric Lighting Acts, the Board of Trade and ordinary municipal foresight, no fear need be entertained that the public may be done out of its rights.

In the Bureau de Contrôle des Installations Électriques, recently formed by the French analogue of our Electrical Trade Section, we have an institution decidedly more worthy of imitation than the custom of concession granting, though, as a matter of fact, there is but a very small chance of it being transplanted. To substitute for Fire Office Rules, Supply Company rules and Institution rules a single code commanding general assent, and for cursory inspections of wiring by miscellaneous gentlemen at odd moments to substitute careful tests at regular intervals by competent and impartial individuals, were a gain alike to wiring contractors and householders. It has been, it is true, our English custom to run our gas-pipes "all anyhow," and to be satisfied with the olfactory test, supplemented on occasions by the crucial experiment of the naked candle flame, but that is scarcely a reason for doing so for all time. In fact, a little more method and precision would be an advantage.

A profound observer of Nature has deduced from a host of disconnected phenomena the great generalisation that it is possible to take a horse to the water, but impossible to make him drink—unless he wants to. Much in the same way, managers of electric-lighting stations on the Continent and in America appear to have discovered that it is easy enough to persuade people to "go in for electric lighting," but that it passes the wit of man to make them pay for it—at any rate, straight off. Thus, at Trent, in the Tyrol, as was recorded in our columns a short time since, the municipal mind in its endeavour to obtain custom and at the same time make the business pay, has hit upon a most ingenious device, which seems worthy of a trial on any not over fertile soil. The low price of 10d. per candle-year, or 6s. 8d. per 8-c.p. lamp per annum is charged, but in order to increase the gross revenue, avoid waste, and save the expense of meters, the Trent authorities reserve to themselves the right of effecting lamp renewals, and charge a tolerably stiff price for the work. In the United States another peculiar custom flourishes, namely, the renewal of the consumers' lamps by the supply companies. At first sight this arrangement would seem to be an instance of the happy self-protective faculty said to be inherent to a civilised society. By all accounts transatlantic central-station managers are not, as a rule, quite so particular about their volts as we are, so that the renewal of lamps by the companies would seem to be a sure specific against over-running; unfortunately, also, the custom almost places a premium on red-hot hairpins. Across the border in Canada a still more free and easy usage has obtained a foothold. From the official report of the proceedings at the second convention of the newly-formed Canadian Electrical Association which was recently held in Toronto, we gather that free-wiring, although regarded with considerable dislike by many Canadian electrical engineers, is deemed by others the only effective way of fighting "a live gas company." So many tales were told at this gathering of the wonderful efficiency of free-wiring in "coaxing people along," that critics were disarmed and confined their criticisms to the custom of charging the work to capital account instead of to working expenses. Opponents were further mollified by the assurance that the free-wiring only included "plain cleat wiring run across the ceilings." As we have frequently pointed out in these columns nothing deters the average London householder from substituting electricity for gas so much as the cost of wiring his house, and the knowledge that his landlord will in most cases reap the benefit of the outlay. What we understood to be an attempt to meet this difficulty was the formation just twelve months ago of the Electrical Fittings Hiring and Maintenance Company with a share capital of over £200,000 and intentions as wordy as its title. So far as we can learn, however, but little has been done by this concern in solving the problem of how to make straight the path that leads to electric lighting. There certainly seems to be a flavour of the small and pushing shopkeeper who throws in a cheap "oleo" with every pound of his 1s. 2d. tea, about this free-wiring, and a device adopted by the Notting Hill Company is, perhaps, more likely to flourish on English soil. This concern has in the case of several extensions of its mains induced those who asked for the extensions to pay the cost of them, the sum advanced for this purpose being repaid in kind, namely, by an equivalent number of Board of Trade units. The consumer gets his light "for nothing" during a period more or less lengthy, and the Company increases its *clientèle* without adding to its capital expenditure. "Notions," transatlantic or continental, may in some instances bear transplanting, and when the tide of lamp-connection begins to slacken and electric-heaters, egg-boilers and flat-irons lose half their attractive force by losing all their novelty, a consideration of foreign practice in these details of the electricity-supply business may not be altogether without benefit.

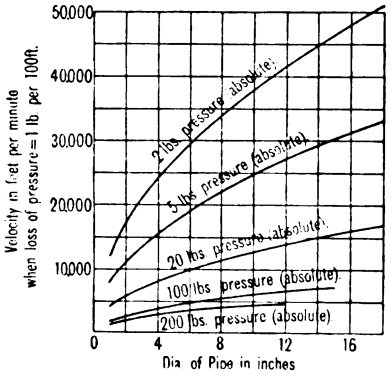
STEAM PIPES.*

It is difficult from the data published to state precisely the laws of the flow of steam in pipes, except that the loss of pressure at certain velocities is known to be inappreciable. Rankine gives 6,000ft. per minute as the velocity which should not be exceeded, while Seaton gives 8,000. It is probable, however, that steam is not far different to other fluids in the laws as to flow in pipes, in which case, as will be seen by the curves given below, the velocities permissible vary enormously, according to the conditions as to pressure, density, and diameter of the pipe.

* All rights reserved. Abstracted from a forthcoming work by Messrs. Geipel and Kilgour (*The Electrician* Printing and Publishing Company).

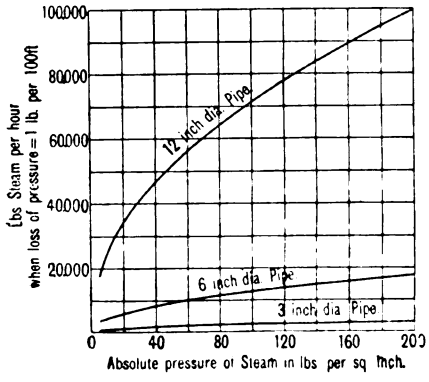
Digitized by Google

The first curve shows at once how the velocity varies according to the size of pipe for a given loss of pressure due to friction. For example, with a 12in. diameter pipe the velocity may be 41,600ft. per minute, with a loss of 1lb. per 100ft. for exhaust steam at 2lb. pressure absolute, while for the same loss of pressure in a similar size of pipe, but with steam at 200lb., the velocity must not exceed 4,770ft. per minute; or, at 20lb., the velocity under the same conditions must not exceed 14,100ft. per minute. Similarly in a 1in. diameter pipe, the velocity for the same loss of pressure varies from 12,000ft. per minute at 2lb. pressure absolute to 1,380ft. per minute at 200lb.



Curve of Velocity of Steam in Pipes.

The second curve gives at a glance the weight in lbs. of steam per hour, which can be passed through pipes of various sizes under different pressures with a loss of 1lb. per 100ft. Thus, a 6in. diameter pipe under the conditions stated passes 2,018lb. of exhaust steam per hour, at 2lb. absolute pressure; at 100lb. pressure it passes 12,700lb., and at 200lb. pressure 17,640lb. per hour. From this the horse-power can be readily deduced if the steam consumption of the engines is known. Under the last conditions of 200lb. pressure, assuming 15lb. of steam to be required per horse-power hour, a 6in. pipe would serve for 17,640/15 = 1,170 H.P., with only ½ per cent. loss of pressure per 100ft. of steam pipe.



Curve showing Flow of Steam in Pipes.

There is little doubt but that the present system of specifying a certain permissible velocity of steam for all conditions as to size of pipes and pressure is, to say the least, a rough and ready rule-of-thumb method; what should be specified is the maximum fall of pressure. However, as this depends not only upon the loss due to friction, but also upon that due to radiation, a maximum velocity may be specified for each size of pipe; for example, if the working pressure is 100lb. absolute, this might be stated as 6,500ft. per minute for 12in. pipes, 4,500 for 6in., 3,000 for 3in., and 2,000 for 1in. It is to be remembered, however, that, for high pressures, a given fall of pressure between boiler and engine represents a smaller percentage of loss than for low pressures. And the difference of a pound or two of pressure due to friction in the steam pipe is of less consequence than in the exhaust, since the initial pressure is only exerted for a fraction of the stroke, while the back pressure of the exhaust remains throughout the stroke; and since for compound engines this difference is increased by the fact that while the initial steam pressure takes place in the smaller cylinder, the back pressure of the exhaust is exerted in the larger cylinder. In addition there is the loss by radiation which increases with the size of pipe and temperature of the steam, demanding moderation in the size of steam pipe which does not hold in the case of the exhaust pipe. In illustration of this it may be mentioned that in 1,000ft. length of steam pipe 10in. in diameter, at a colliery in Durham, it was found that the heat lost by radiation cost about £100 per annum.

The following may be easily committed to memory *In any pipe the loss of head in a length equal to 33 diameters equals the head theoretically necessary to produce this velocity.*

Approximate Rule for Sizes of Steam Pipes.

Piston speed in ft. per minute.	Area of steam pipe in sq. in.
600	$\frac{1}{10}$ area of piston.
500	$\frac{1}{12}$ "
400	$\frac{1}{15}$ "
300	$\frac{1}{20}$ "
250	$\frac{1}{25}$ "

For small pipes larger areas should be used, particularly if the steam pipe is long.

A TELEPHONIC METER.

At the Electrical Congress at Frankfort in September, 1891, Dr. Strecker, chief inspector of the German Government Telephone Department, read a Paper in which he threw out the idea of measuring the telephonic conversation carried on by each individual subscriber, thus enabling telephone companies to check the misuse by non-subscribers on the one hand, and on the other to make their charges in some degree commensurate with number and length of conversations indulged in. On the basis of this principle the German Government subsequently invited designs for a telephonic meter that would allow the registration of each conversation

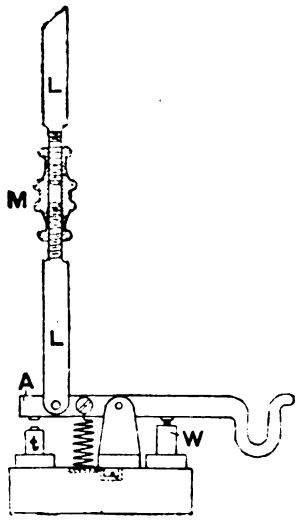


FIG. 1.

from the time of unhooking the receiver to the replacing of the same, and to fulfil the conditions laid down, Messrs. Mix and Genest have devised the contrivance illustrated herewith.

The apparatus consists of a clockwork movement having a starting and stopping arrangement operated by unhooking the receiver, and replacing the same. To the switch A (Fig. 1) a guide rod L is connected, the length of which can be regulated by a nut M. At the free end of L there is an arm F provided with a catch (Fig. 2), which rests on a pin *s* fixed on the pendulum P. The catch is so shaped that the pin *s*, when the pendulum is swinging, lifts the hook when the latter is lowered, and the motion of the pendulum is arrested. When the receiver is unhooked, the switch A is pulled down by the spiral spring, the bell-contact W is broken, and the line-contact *t* is made. This movement lowers the rod L, and the catch is raised to the position indicated by dotted lines, thus releasing the pendulum. It will be seen that the hands of the clock will move as long as the receiver is unhooked, and will be stopped when the receiver is replaced. To switch off the instrument when the clockwork is not wound up and to remind the

Digitized by Google

subscriber, there is provided an indicator N (Fig. 2), which is worked by utilising the reduction of tension in the clock spring to limit the movement of the automatic switch. This is done by fixing the catch K, not to a fixed pin, but to a movable lever H (Fig. 2), which moves on the pivot of the barrel itself. The lower end of the lever H moves between two spring buffers, *p* and *p*, of which *p* is provided with the stronger spring. When the clock spring is run down and the pressure taken off the lever H, the lever moves towards *p*. This movement brings a catch R into action, drawing it into a notch E effected in

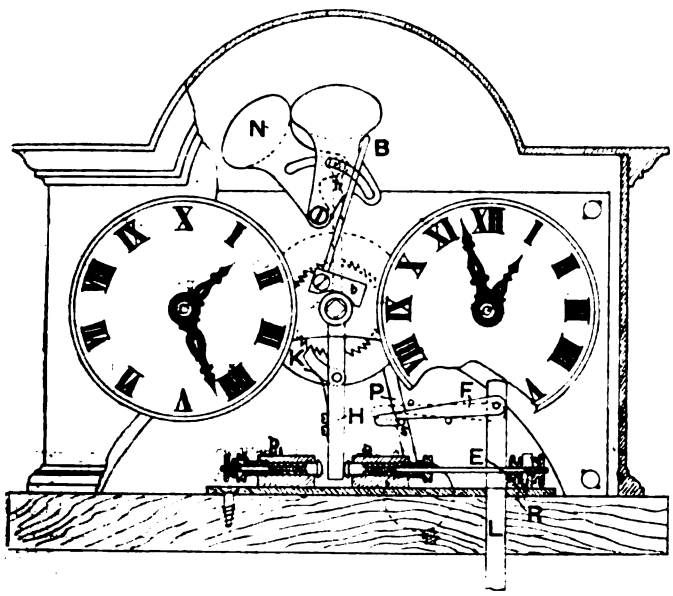

FIG. 2.

the rod L. This locks the rod and the switch. The lever H carries an indicator disc N on its extension H, which, when H moves over, brings the disc into view behind a glazed aperture, giving the warning to wind up the clock. When the clock key is inserted the small lever *b* is pressed sideways, bringing the arm B into action, and replacing the indicator disc.

THE DISTRIBUTION OF POWER BY ALTERNATE-CURRENT MOTORS.

The following is an abstract of the discussion on Mr. Albion T. Snell's Paper, which took place on Thursday evening last week at the Institution of Electrical Engineers. Speakers who have returned their proofs revised have asterisks placed against their names :—

*Mr. SPARKS said he had obtained permission to bring before the meeting two single-phase motors designed by Mr. C. E. L. Brown. The larger one was of the synchronous type, and the smaller one of the non synchronous type. The synchronous motor, although comparatively well known, was not described in Mr. Snell's Paper. This motor had no great torque at starting, so had to be started when the belt was on the loose pulley, and the motor had to be placed in such a position that the brushes made contact each one with a segment. It was very easily started indeed, and he believed everybody who had tried had been able to do it. The field-magnets consisted of four poles, each one with a coil on it, the coils being two in parallel, and supplied the current through a commutator. The armature stampings were perforated, and wires were threaded through these perforations. The electromotive force of the synchronous motor was 92 volts at 40 ∿. To the best of his knowledge there were no installations working at so low a periodicity in this country at the present time. On starting the motor the armature and field-magnets were placed in parallel, and a fixed resistance was put in series in the field, the current being supplied through a choking coil. If the motor was in the proper position it would start when on the loose pulley. It went away directly at a fair speed until it reached a certain definite speed, without any further tendency to increase, when part of the regulating choking coil should be cut out. Then it went faster, and another section of the choking coil must be cut out, until the motor attained a speed of upwards of 90 per cent. of its synchronous speed. The motor then began to make a kind of beat. The field-magnet should now be cut out altogether, and at the same time connected in parallel with a few turns of one armature coil. Directly the resistance was cut out, supposing the motor were running at from 80 to 90 per cent. of its synchronous speed, it as it were galloped up and got into synchronism in a very remarkable manner. As soon as it attained synchronous speed the belt should be transferred from the loose pulley to the fast one. Then the motor could have the load thrown on it suddenly—not only its nominal load, but three times its rated load—without in any way dragging it out of synchronism. The motor ran at 1,200 revolutions at 40 ∿. That motor had been used for several weeks to drive part of the factory in Charterhouse-square, and that type of motor was used up to a size of 10 H.P. The second motor was one which should be of great interest. It was of the non-synchronous type and worked with 120 volts at 40 ∿. Its armature consisted of a number of stampings, and these all had holes through them, and through each hole was a carefully-insulated copper rod. The whole of these were connected up at both ends, so that they really had a number of short-circuited coils. There were no brushes of any kind, and the field-magnet winding was similar to the armature winding of the synchronous motor. There were two sets of coils ; one set was always in use when the motor was in work, and the second was only in use when the motor was starting. In order to start the motor the current was switched straight on to the field-coils, which were connected in parallel. On starting, the second set of coils was connected in series with a condenser of extremely simple construction, consisting of a series of iron stampings separated by wooden blocks, the intervening space being filled up with a 10 per cent. solution of caustic soda. The speed ran up practically to that of synchronism, although it was a non-synchronous motor. The motor when loaded to 1 B.H.P. took 11 amperes at 120 volts, or 1,320 *apparent* watts. When giving during short periods 2 B.H.P., it took 2,760 *apparent* watts. This meant a return in B.H.P., in the case where it was overloaded, of 54 per cent. of the *apparent* watts ; when giving 1 B.H.P., the return was 56 per cent. of the *apparent* watts. With a 10-H.P. motor of this type, weighing between 9cwt. and 10cwt., which was daily working in a sawmill, giving over 15 B.H.P., the commercial efficiency of the normal B.H.P. was between 88 and 90 per cent. of the *real* watts supplied to it, the difference between the real and the apparent watts being 12 per cent., or 80 per cent. of apparent watts appear on the brake. When taking the maximum power from that motor the percentage drop in speed value from that of synchronism was a little over 3 per cent. ; so it was practically a constant speed, although non-synchronous. He would put before them a comparison between a three-phase motor, the particulars of which had been published by Herr Dobrowolski in the *Elektrotechnische Zeitschrift* of March 31st last, and a 1-H.P. single-phase motor tested by Messrs. Brown and Boveri ; if not the actual motor before them, it was a fellow one to it :—

	Three-phase motor.	Single-phase.
Nominal output	1 B.H.P.	1 B.H.P.
Pressure	104 volts.	120 volts.
Current (no load)	7·8 amperes.	6 amperes.
Current (full load)	13·85 amperes.	11 amperes.
Apparent watts	1,440	1,320
Frequency	50	42
Speed (no load)	1,490	1,250
Speed (full load)	1,375	1,210
Per cent. drop of speed	7·22	3·2
Weight of motor	207lb.	141lb.
Temperature rise	40-50°C.	25-30°C.

Motors of that type were running, or shortly would be running, at Baden, Lucerne, Cologne, Dresden, Rome, Ragaz, Chur, Furstenfeld-Bruck, Intra, Grenoble, and other places, and he thought Mr. Brown was to be congratulated on the very remarkable results he had obtained. The special points of the motor were the total absence of the collector-commutator, the ring form of oiling, the ease of mechanical construction up to large sizes, the minimum attention and repairs required, and the great torque obtained at starting. Of course, many had worked in this field, but it was pointed out by Mr. Brown in his letter to *The Electrician* that although many had worked in a similar direction, none had put into practical use any similar motors.

*Mr. SWINBURNE said, like everybody else present, he had been exceedingly interested in the Paper and in the whole subject of alternating motors. He had just received a great surprise from Mr. Sparks, who had described a pair of motors at great length as being quite new to England. This was a surprise, because, curiously enough, the first motor described was made by Mr. Brown, with whom his (Mr. Swinburne's) firm were working, and the English, German, and Swiss patents were all taken out by his firm in his (the speaker's) name. It was naturally a surprise, therefore, to find the motor, as it were, reflected back from Switzerland without his name attached to it, when he thought it was really his invention. The first difficulty which arose in running this synchronising self-starting motor was due to the sparking at the commutator. As early as 1888 he ran a motor of that sort when with Messrs. Crompton. He thought that was probably the first synchronous small motor of that type ever run in this country. It was not a motor one could put into commercial use. Since then he had been working a great deal at the subject, and whilst he had made some that would start, he had also made some that would not. He had not yet, however, made a motor that he would consider himself justified in putting on the market. They must remember that the motor just described was made for a low frequency. It would not work so well when they reached high frequencies. He did not know that it was of much use working out a motor for a frequency of 40 in this country ; they must start with 100, and if they wanted to develop largely they must have it up to 133 for America. There was a great difference between a frequency of 40 and one of 133, as anyone who had experimented largely with motors would know. The chief difficulty with motors had been, not the difficulty of starting, though that, of course, was a serious one, but the difficulty of getting them to run without taking a fairly large current with no load. These motors took 7·8 amperes with no load and 13·85 amperes with full load. It must be remembered that that had to come through the transformer, and it had also to come through the meter, and it would be a difficult thing to place a motor in England that took half-current at no load. He did not think, unless an alternating

Digitized by Google

motor would run under nearly the same conditions as a direct-current motor, that it was of much use putting it on the market in this country. They could bring it forward, and get accounts of it in all the various papers, and make a fuss, but he did not think it was a practical solution of the difficulty. With regard to the other motor mentioned by Mr. Sparks, he thought they ought to give credit to whom it was due in that case also, and that motor, he believed, was invented by MM. Hutin and Leblanc. Other people were working on the same thing. Boucherot did some theoretical work. Tesla had patented it more recently, and so had Elihu Thomson; but when they took that motor they would find that the necessity of putting a condenser in series was a troublesome thing. People did not want condensers put in their houses. A condenser also had other disadvantages. He did not think they ever would solve the alternating motor problem until they made a machine which was self-exciting, not excited by the reactions of one of the parts on the other. All those motors, when examined carefully, would be found to be machines which had field-magnets entirely excited by their own armature reactions. That was an evil. He would like to refer to the supposed advantage of the double and triple current He thought there was a great deal too much being said in favour of the double and triple currents. The engineer who ran an alternating station asked the inventor for an alternating-current motor; the inventor brought forward something which he said was an alternating-current motor, but it was at most a sort of quibble, for it was not an alternating-current motor at all in the sense in which the engineer wanted it. The engineer had a circuit with an alternating-current system of distribution, and wanted a motor to run on that; he did not want a motor to run on a totally different circuit which he had not got. But that was what had been offered as an alternating-current motor. He was quite aware that the double and triple current had some advantages over the single current in ease of starting and ease of transmission of small powers from place to place at high pressures. The only advantage with double currents was in starting small motors. If an installation consisted entirely of motors, which would be very curious, then it might pay to use double or triple-current motors; but if the installation consisted of lamps and so on, it would probably be best to transmit a single alternating current over the long distance, and then convert it to direct current, and be done with it, not run a complicated system of which no one could measure the power or anything else, and which there was great difficulty in balancing. He would now come to a question which was half theory and half nomenclature—that was the question which was the armature and which the field-magnets. Ever since this question came up he had been in a minority of one as to which was which. He did not know how the orthodox people explained the matter. He would propose a very simple definition, which agreed with dynamo practice so far as it had gone; that was to say, the field was the part of the machine which had the induction in the iron constant, or in the same direction, and the armature was the part where the alternating current was. It must be remembered that, even in a direct-current machine, the current in the armature was alternating. He would like to point out that the alternating current induced in the field-magnet coil, even if short-circuited, was not an alternating current of the same frequency as the current in what he called the armature. If it was a triple-current machine the frequency was six times that of the armature current, and if it was a double-current machine it was four times. That was rather an important point. There was one other matter he would like to refer to. The power, according to Dr. Hopkinson's equation, was always E times a long expression, which it was not worth while giving, E being the electromotive force of the machine at no load. The machines in question had no excitation whatever, and could, therefore, give no electromotive force at no load, so, according to Dr. Hopkinson's theory of the action of dynamos and motors, neither the "drehstrom" nor any other similar contrivance could work. He, therefore, looked upon this as a standing confutation of the self-induction theory of dynamos.

*Mr. W. M. MORDEY thought, whatever developments might take place in alternate-current power transmission, it would be found that for large powers synchronous motors would have advantages. Mr. Snell said the torque of such a motor must not exceed a certain value, or the machine would stop. He (Mr. Mordey) thought that criticism might be applied to most motors. In the Paper which he (Mr. Mordey) read a few weeks ago he gave some figures showing that the power factor with synchronous motors was very nearly as high as with good closed-circuit transformers. The idle current in the mains, therefore, was not a difficulty. As to the objection that motors must be designed not only with reference to the pressure but also with regard to the frequency of the current, he did not think that was a very great difficulty. Another objection in the Paper to alternate-current synchronous motors was that they had dead points in each period. That was true, but these dead points were very little ones. He thought the fact that steam engines had dead points had not been found an insuperable objection in their case, and he did not see why it should be in the case of synchronous motors. They had been told that in England they had been very backward in adopting "drehstrom" working. He thought, as a matter of fact, English electrical engineers had regarded the two or three-phase motors as merely a make-shift, and they had simply sat still and waited for some one to develop motors that would run with ordinary lighting mains, and he agreed with Mr. Swinburne—and he supposed with most people who had studied the subject—that until motors were produced that could be run on the ordinary alternate-current mains, the same mains as were used for lighting, motors would be very little used except for special cases. The difficulty with regard to frequency was, he thought, a temporary one. In a little while they would have motors that would run at 100 or 133 ∿. This demand for motors on alternate-current mains was one that they were constantly coming across, but they were not coming across it, he was afraid, because of any real demand for motors, but for what one might call electioneering reasons. When people were thinking of putting down lighting plants they were led to say "Oh, but you cannot put down motors on your circuits." It was of very little use to say to them that if they looked around they would not find that it really mattered much. He believed if they had alternate-current motors to-day as good as the direct-current motors which they had on ordinary installations, there would be no great use for them. The whole question was supposed to turn—and Mr. Snell had alluded to that, although not very pointedly—on the question of periodicity, and he wanted to say a few words about it, as there was a disposition to go down to 40 or 50 ∿, instead of 80, 90, 100, or 130 ∿. He was reminded of a remark made by Mr. Brush a little while ago to an eminent member of the Institution, who was explaining to him the advantages of using 20 or 25 ∿ for some scheme that he was considering. Mr. Brush said, "Oh yes, that's right! Get a little bit lower, and you will have a good honest direct current." He (Mr. Mordey) really thought that when they got down to 20, 30, or even 40 ∿, they might just as well have a good, honest direct current, because the disadvantages of alternating currents at low periods were so great that very little could be said for them in comparison with direct-current working. The real reason, or one of the principal reasons, why 40 ∿ periods had been so largely used on the Continent might be, he believed, traced to the difficulty of designing machines of certain types to work at a greater rate. The Ganz machines were, perhaps, the most largely used on the Continent, and he believed they were worked at 40 ∿ simply because the machines had a lot of iron in them, and there were electrical and structural difficulties if any attempt were made to use them at higher rates. Now, in alternate-current distribution the key to commercial economy was to be found in the transformer. To make a transformer equally good and equally efficient at 40 or 50 ∿ as at 100 ∿ was very difficult. The transformers were not only costly, but they were wasteful. It was not, as he had been told, a question of design. He had been told that he must not use a 100-period transformer at 40 ∿, or a 40-period transformer at 100 ∿, but must design a transformer properly, put more iron in in the one case, and so on. Well, he had taken a 40-period transformer made by most experienced makers, and he had run it at 100 ∿, and, of course, he had found that, although this had been designed specially for working at 40 ∿, it was very much more efficient working at 100 ∿ than at 40. Then he had taken a 100-period transformer and run it on 40-period mains and burnt it up. So he thought that showed there was no basis of truth in the argument that they could design transformers equally well for any period. He thought if they took any ordinary transformer and considered the magnetising-current curve, they would find that from 40 to 80 or 100 ∿ they would decrease the current very much, and not only did they increase the current, but the power factor was not improved as they went down in periodicity. The motor difficulty was merely a temporary one. Mr. Sparks had shown it that night half solved; if they waited a little while they would see it solved altogether. How important efficiency was was not properly realised. It was thought a few watts more or less did not matter very much. But if they reckoned out the power spent in magnetising transformers, and took the very lowest estimate—let them take, if they liked, one penny per horse-power per hour—they would find that each watt continuously expended cost a shilling a year, and there was no station in this country that could produce a watt continuously for a shilling a year in that way. They might take it that two or three shillings a year was thrown away on every watt wasted, and if they worked at 40 ∿ they threw away more money, and spent more money on their transformers to start with. And really, what applied to transformers would, he believed, be found to apply to motors.

*Mr. KOLLE asked to be allowed to supplement Mr. Sparks' remarks. Mr. Brown had already working at Chur, in Switzerland, a 3-H.P. single-phase self-starting non-synchronous motor working at 70 ∿, and they had also at the Ferranti works at the present time a single-phase self-starting synchronous motor which worked on the London Electric Supply Corporation circuits of 85 ∿. A further advantage of the Brown motor was the small clearance between the armature and field magnets.

*Prof. AYRTON said Mr. Snell's Paper raised a very interesting point indeed with reference to the use of motors on alternate-current circuits. As far as he knew, Prof. Forbes was the first to publish the idea of constructing a motor in which they commutated the current through the field, producing, of course, sparking at first until they got up the right speed, when there was practically a pulsating direct current through the field. That must have been in 1882 or 1883. With reference to the question of field and armature, the suggestion which Mr. Swinburne had proposed was a suggestion which Prof. Perry and he had made in their much abused paper on motors at about the same early date, 1881 or 1882. There they said their motor was a motor with a stationary armature and a rotating field, and they said distinctly that by field they meant the part of a machine which had a direct current round it, whether it rotated or not, and by armature the part which had the current alternating in its coils, whether it was stationary or not. But the definition was not quite so simple when they came to a "drehstrom" motor, because if there they called the part of the motor in which the current alternated the armature, then, as in that case both parts of the current alternated, there would be two armatures and no field-magnet. The only way to improve the definition in a machine with a varying current in each part was to call the field the part in which it varied the least, and the armature the part in which it varied the most. In advising a town a little while ago to use alternate currents, he told them the motor question was not worth considering, and that if anybody wanted to use an alternate-current motor it would pay the company to supply power at a penny or twopence per unit cheaper to them to compensate for any want of efficiency in the alternate-current motor. The advantages of using transformers for distribution of electric-lighting current were so great in a scattered town that the small disadvantage of the inefficiency of alternate-current motors was not really worth considering. Mr. Kapp at the last meeting had pointed out one reason, viz., the armature reaction, why the

Digitized by Google

theoretical variations in the field of a "drehstrom" motor were so great. Another cause was that the calculations applied merely to the variation in the exciting *current*. When iron was magnetised the induction did not vary nearly as much as the current, and thus when there was a variation of 14 and 20 per cent. in the exciting current, that did not correspond to anything like the same amount of variation in the magnetism, which was, of course, the important thing. In speaking of the series or open circuit, Mr. Snell spoke of the potential difference at the terminals of the coil lagging 30deg. behind the potential difference between the mains. That was a mistake. It should be that the potential difference at the terminals of a coil with series winding was 30deg. in advance of the potential difference between the mains. It was not true, as Mr. Snell seemed to infer, that the output for a given weight of material was less in the three-phase system, assuming no self-induction, than with the two-phase. This was pointed out some years ago by Dobrowolski. With the three-phase system of transmission they had three wires on the poles, each wire carrying a certain maximum current, the insulation being such as to allow a certain maximum potential difference between mains. They increased the cost of the wires by 50 per cent., but they increased the output by 73 per cent. over that of two wires with the single-phase current. The speaker then proceeded to examine the Paper in detail, pointing out certain errors on the formulæ, and concluded by remarking that the Paper contained a number of direct results, and Mr. Snell had endeavoured to put the well-known theoretical consideration about "drehstrom" motors before them in a simple fashion, and, therefore, he thought they ought to thank him for his contribution to the subject.

Mr. SNELL, in replying, said the subject bristled with difficulties, and he was afraid he could not do justice to the various speakers who had done him the honour of criticising his Paper by immediate reply, and he must take time to think out some of the questions they had raised, so as to make a suitable answer in the proceedings of the Institution. But there were one or two points he should like to refer to at once. Mr. Sparks had put before them a very interesting motor. He did not agree with Mr. Sparks that so much credit was due to Mr. Brown. It was, after all, as Mr. Swinburne had said, nothing but the development of Elihu Thomson's motor. He was speaking now about the synchronous motor. With regard to the non-synchronous motor, that had undoubtedly advanced the subject very materially; but, as he had said in his concluding sentence, the problem of alternate-current motors suitable for running on ordinary electric-lighting mains was not satisfactorily solved. He thought the majority of speakers that evening bore him out on that point. At the time he wrote the Paper he was thinking very much about motors for use in coal pits, and there the question was not so much a motor which would work with high efficiency as a motor which would work without sparking, and the little motor shown on the table realised that condition. If the efficiency of that motor was only 60 per cent. it would do for a good many purposes in a coal pit, and if a larger motor could be built with an efficiency of 70 to 80 per cent. they might be said to have advanced the question of the application of power to mining work very materially. Lighting in the coal pit was of secondary importance altogether, and if the light fluctuated a little it would be of no consequence. He would like to say a few words about the definition of field and armature. He had taken the definition which he believed was the Continental one; that was, he called the armature that part which had the currents induced in it, and he called that part the field which had the current supplied to it. That being the case, he called the stationary part of Mr. Brown's motor the field. He called the part that revolved the armature, because it had currents induced in it by virtue of those currents. But, undoubtedly, from purely theoretical considerations, the suggestion that Mr. Swinburne had made, amended by the further improvements of Prof. Ayrton, was well worthy of consideration, and probably those terms would hold in future; but for his Paper, and for the present, as he had clearly defined the meaning of the terms he had used, he thought there was no need for confusion.

The CHAIRMAN (Mr. Alexander Siemens), in according the thanks of the Institution to Mr. Snell, said he could not help emphasising one point which had been brought out, and that was that the English engineers should not be too much blamed for holding out in this question of alternating currents. They were, after all, a body of practical people who had to apply science to everyday life, and the practical question which to a great extent governed what they were to do and what they were to investigate was the eternal question of £. s. d. His firm had worked a great deal upon rotary motors in Berlin, but they had not done so much here, because it was obviously unnecessary to go into a separate set of experiments while they had the experience of Berlin at their disposal. In every case where they had to work out problems for transmitting power to a distance they had given the exact problem to their Berlin house and had asked them to work it out, and up till now they had not had one instance in which they could not carry out such a problem just as well either by direct currents or by the ordinary alternating-current machines as they could have done by the rotary currents.

PHYSICAL SOCIETY.

At the meeting on April 28, 1893, Prof. W. E. Ayrton, F.R.S., Past-President, in the chair, Mr. E. C. RIMINGTON read a Paper, on

"Luminous Discharges in Electrodeless Vacuum Tubes."

The luminous rings produced in exhausted bulbs and tubes by discharging Leyden jars through coils surrounding them, had, he said, been attributed by Mr. Tesla (*Electrical Engineer* of New York, July 1, 1891) to the electrostatic action of the surrounding wire rather than to the rapidly varying magnetic induction through the rarefied gas. The present Paper describes several experiments bearing on this point, which lead the author to conclude that varying magnetic induction is the chief cause of the luminous rings. They also show that a superposed electrostatic field greatly assists the production of the luminosity. Most of the experiments described were performed before the meeting, some of the effects being particularly brilliant. In one experiment an exhausted bulb (Fig. 1) was placed within a coil *a b*, connecting the outside coatings of the Leyden jars A and B, and placed between two metal plates C and D, which could be connected at will with the outside of either jar. The spark gap S between the inner coatings was then arranged so that no luminosity was seen in the bulb. On connecting one or both the metal plates with the jars by means of the wires *e f* in such a way as to increase the electrostatic field through the

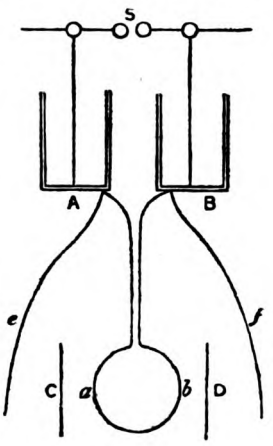

FIG. 1.

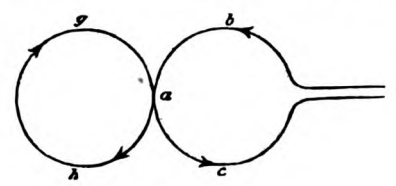

FIG. 2.

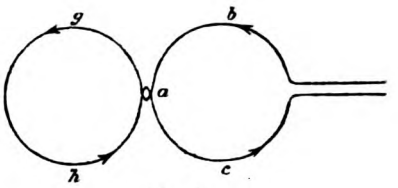

FIG. 3.

bulb, bright rings immediately appeared. An electrostatic field produced by a small induction coil connected to a piece of tinfoil on the bulb caused the rings to form at irregular intervals when the discharge of the jars and coil happened to be properly timed. In another experiment two loops of wire (Figs. 2 and 3) in series were used, and when put on the bulb in such a way as to produce a large magnetic effect but small electrostatic field, bright rings appeared; but if the magnetic effects of the coils opposed each other whilst the electrostatic field was increased, no rings were seen. Putting the wire (Fig. 3) on a bulb, a discharge was obtained (Fig. 4) like the sector of an orange.

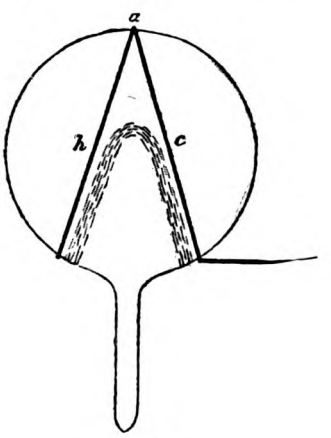

FIG. 4.

The subject is treated mathematically at some length in the Paper, the times at which the maximum values of the current, the potential difference between the outsides of the jars and the rate of change of current occur, as well as the values of their successive maxima, being determined. The influence of "Size of Jars" is next considered and the time-integral of rate of change of current, on which the effect on the eye depends, expressed as a geometrical series. Taking an approximation, the author shows that the time-integral is roughly proportional to the fourth root of the capacity. Large jars are, therefore, theoretically only slightly better than small ones, and this agrees with observation.

On the subject of "Apparently unclosed discharges," such as are seen when discharges pass through a coarse spiral wound on an exhausted tube, the author said he had observed that the discharges were really closed, but the return part much diffused and of feeble intensity. Experiments were exhibited showing that under some circumstances an exhausted bulb acted like a closed metallic circuit, whilst under other conditions dissimilar effects

Digitized by Google

were produced. Another experiment was shown in which a faint luminous ring, produced by a single turn of insulated wire round a bulb, was apparently repelled on touching the wire with the finger.

The author also showed that fan-shaped luminosities could be produced by rotating an exhausted tube in the electrostatic field produced by a charged ebonite or glass rod.

Dr. SUMPNER, speaking of the apparently unclosed discharges, pointed out that they might be closed through the wire forming the primary circuit, in the same way as a coil of a transformer might be arranged to act partly as primary and partly as secondary.

Prof. S. P. THOMPSON thought an electrostatic field would aid a discharge even if its direction was not the same as the E.M.F. due to varying magnetic induction. Planté had found that vacuum tubes through which 800 cells were insufficient to produce a discharge immediately allowed a discharge to pass when a rubbed ebonite rod was brought within about 10 feet distance. This effect was found to be independent of the direction of the disturbing field. Analogous effects had also been observed by Prof. Schuster, and described in his Bakerian Lecture.

Mr. E. W. SMITH regarded the stresses set up in the medium as cumulative, a very slight cause acting on a substance already strained nearly breaking point being sufficient to cause breakdown.

Mr. BLAKESLEY inquired if the effects were the same if the induction

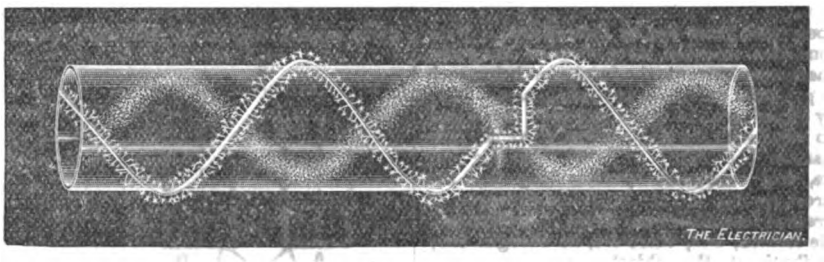

FIG. 5.

Mr. A. P. TROTTER, after referring to Dr. Bottomley's researches, said it was important in discussing such experiments to distinguish between electrostatic and electromagnetic effects. In Mr. Campbell Swinton's experiments the luminosity always appeared to get as far away from the wire as possible, and to be at right angles to it, whereas in Mr. Rimington's the luminous portions were close to the wire. With a view to puzzling the discharge in Mr. Swinton's tubes he had made a right-angled bend in the spiral surrounding the tube, the result of which (Fig. 5) was to make the luminosity discontinuous, one end of the break being bifurcated. In all Mr. Swinton's experiments brilliant brush discharges surrounded the wire.

coil, used in one of the experiments, was replaced by an electric machine, and whether the direction of the field so produced influenced the result.

Mr. W. R. PIDGEON said closed circuits were necessary, and he had found it very difficult to produce discharge in tubes unless the ends of the primary wire were brought together.

In his reply, Mr. RIMINGTON said each turn of the luminous spiral formed a complete circuit of itself. The phenomena observed by Mr. Campbell Swinton were quite different to those he had shown, and due to different causes; Mr. Swinton's spirals were reversed, and were due to phosphoresence of the glass.

LEGAL INTELLIGENCE.

Elgood v. General Electric Power and Traction Company (Limited).

An action to recover damages for injuries caused by the alleged negligence of a person in the defendants' employ while navigating one of their electric launches on the Thames was tried on Friday and Saturday last, in the High Court, before Mr. Justice Grantham and a common jury.

Mr. Lockwood, Q.C., and Mr. G. Elliott were counsel for the plaintiff; Mr. Waddy, Q.C., and Mr. Brunner for the defendants.

Mr. LOCKWOOD, Q.C., opened the plaintiff's case, and called

Mr. ERNEST CRAWSHAW ELGOOD, the plaintiff, who said he was a member of the Bar and a member of Lloyd's. On July 6, 1892, he was with a party of friends at the Molesey Regatta, and they were turning to go in to the Castle Inn landing-stage when he heard a cry, "Look ahead, launch!" The launch struck their punt on the port side, and rose over the gunwale. The water came in rapidly, and the punt turned turtle and threw its occupants into the water. He held his wife up until assistance came from the shore. She was very ill all night. There were no lights on the punt. The Board of Trade required one man only to be on board the launch. The man in charge of the launch stood in the bow.

Mr. ORLEBAR said he was the owner of the punt. He saw the launch coming round when she was forty or fifty yards away. Seeing there was a possibility of a collision he shouted, "Look ahead, launch!" but no notice was taken, and the motive power was running when she struck the punt. The launch did not alter her course or speed. There was no fixed rule in regard to river traffic, but a launch should give way to a boat.

Mr. WADDY, for the defence, said the launch was going slowly, in consequence of the motive power being nearly exhausted. One man was amply sufficient to navigate the launch. A good look-out was being kept. It was a dark night, and the punt was in the dark shade under the bridge without a light. The whole fault was Mr. Orlebar's.

HERBERT WILSON said he entered the service of the defendants at Easter last year, and was constantly in charge of one of their electric launches. On the night of the accident he was in charge of the launch "Theta." He carried lights. As he approached Hampton he was going from two to three miles an hour, going at half-speed. It was a dark night. He was standing right forward in the launch. The switches and wheel were forward, and all within his reach. On approaching the bridge a black object shot out from the bridge in the way of the launch. He reversed, but too late to avoid collision. One of the gentlemen caught hold of the bow of the launch, which was going astern, and capsized the punt. Before he could put the lever to reverse he had to turn a lever to cut off the current. In order to reverse, it required three actions—first, to cut off the supply, next to reverse, then to put on the supply.

ROBERT TAGG, boat proprietor, Molesey, said on the night of the accident he was on the landing-stage. He did not see the launch before the collision. He did not think it proper watermanship for a punt without a light to come through the third arch and cross to the second.

WILLIAM PEARCE, the defendants' foreman, said defendants had eight boats of the "Theta" class, which were under the care of one man. One man was quite sufficient to manage a launch of that class.

Mr. Justice GRANTHAM, in summing up, said the question was whether the defendants' servant was negligent, and, if so, were the plaintiffs also negligent. If there was negligence on the part of the defendants and not on the part of the plaintiffs, then the defendants would be liable. There was no doubt that the punt could not be seen at any distance. They ran considerable risk going about on the river at night without lights. Had the defendant time to pull up or do something after he heard the shouting? There was no negligence on the part of the defendants' man in not seeing the punt before the shouting, because it was a low dark object in the shade of the bridge. If the defendants' man could have pulled up in the time after he heard the shout, and did not, then the defendants would be liable.

The jury found a verdict in favour of the defendants.

Fowler, Lancaster, and Co. (Limited).

In the Chancery Division on Wednesday last week the case of Fowler, Lancaster, and Co. (Limited), came before Justice Vaughan Williams. The petitioners were creditors for a debt of £159, due on a dishonoured bill, and they petitioned for an order for compulsorily winding-up, notwithstanding that voluntary liquidation had been resolved upon.

Mr. Hart appeared in support of the petition; Mr. Farwell, Q.C., appeared for the Company and opposed the petition.

Mr. HART said the Company had carried on business at the Albert Works, Graham-street, Birmingham. The ground of the petition was insolvency and failure of the Company. The failure was attributed to lack of sufficient capital to work the business economically, general depression in trade, and the crisis through which the electrical trades had lately passed. Fowler, Lancaster, and Co. was incorporated in 1890, with a nominal capital of £22,000, of which £17,820 was subscribed. The Company was now in a state of hopeless insolvency, with unsecured debts amounting to £6,500 and debentures £7,000. Under these circumstances the unsecured creditors thought their interests would not be sufficiently protected by voluntary liquidation conducted by the nominee of the debenture and shareholders, and asked the Court for a compulsory order.

The petition was ultimately adjourned for evidence as to the formation and working of the Company.

Vestry of St. Margaret and St. John v. Queen Anne and Garden Mansions (Limited).

On Thursday last this case came before Justices Day and Bruce in the Queen's Bench Division. It was an appeal by way of special case from the decision of Mr. Sheil, Metropolitan Police magistrate, who had decided that the cinders and ashes produced by the Company which supplied Queen Anne's Mansions with the electric light, &c., were not trade refuse.

Mr. Finlay, Q.C., and Mr. Percy Gye appeared for the Vestry in support of the appeal; while Mr. Boyle opposed it.

Mr. FINLAY, in support of the appeal, said the Company which produced the refuse was called the Queen Anne's Mansions Lighting and Heat-

Digitized by Google

ing Company (Limited), and held a lease for a term of eighty years of a piece of ground under the courtyard of Queen Anne's Mansions. The Company supplied electric light to the mansions, and had power to supply it to any other building. Vestries were bound to remove house refuse, but in the case of trade refuse they were entitled to be paid for removing it. The question raised by the case was whether the cinders and ashes produced by the Company in supplying the mansions with electric light were refuse produced in the course of a trade. The magistrate was of opinion that they were not, but he (the learned counsel) submitted that the magistrate was wrong, and that his decision ought to be reversed.

Mr. BOYLE, in opposing the appeal, said the Company was formed solely for the purpose of supplying hot water, hot air, and electric light to Queen Anne's Mansions, and, therefore, could not be regarded as a company carrying on a trade. Therefore, the cinders and ashes produced on the premises were not trade refuse.

Mr. Justice DAY said in his opinion the cinders, &c., were essentially trade refuse, and, therefore, the appeal would be allowed.

Mr. Justice BRUCE concurred.

Brush Electrical Engineering Company (Limited) v. Sage and Co.

This case was in the list to be heard by Mr. Justice Day in the Queen's Bench Division on Tuesday. When the case came on, counsel for the plaintiffs stated that it had come to their knowledge that the defendants were bankrupt, and upon that account he would withdraw the plaintiffs' claim.

CORRESPONDENCE.

SINGLE-PHASE ALTERNATING-CURRENT MOTORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I do not think that the letter of Mr. Brown in your issue of March 31, 1893, affects my contention that motors, working on a principle, the discovery of which he had stated was the result of his own observations, were known in the art. I called attention in my letter, to which he refers, to my patent 407,844 in support of my assertion. I also stated that I had experimented with various forms of these motors, and I will now be more explicit in relation to them. One of my first motors had the relation of its field coils and armature as 1 : 3—that is to say, the field circuit through which alternating currents were passed, being single, there were three armature circuits closed when running. Other motors made in 1889 have numerous armature circuits, in relation to the field coils. I tried smooth winding, but always found the projection armatures more effective. None of these motors were synchronising motors, as Mr. Brown seems to think, but behaved just as he has stated in the words "only when running light will the speed approach synchronism. When loaded the speed of the rotating park sinks so far below synchronism that the current produced by this difference of speed gives the necessary torque. The extent of this drop depends on the form of the rotating part, &c.," when referring to his modification.

In my patent the statement is made that "many arrangements of coils and cores may be used." Mr. Brown in his last letter says, referring to the work of Mr. Tesla and myself, "but I would point out that certain points in their machines were inherently defective, and that it was only by remedying these that I have been able to produce a practical single-phase motor." In other words, as I understand it, Mr. Brown in 1892 has remedied defects of motors the principles of which he now admits have been known a long time since. If this be so then my original contention remains. Further, I submit that the remedies applied are just those which have been applied to all classes of electrical machinery in the past few years—a more intelligent use of iron projections than formerly. I have the greatest admiration for the skill and engineering ability shown by Mr. Brown in his work, but must insist on the identity of principle of his motor and those which preceded it.

In the statement at the close of his letter regarding the high frequencies in vogue in America, and "that there was nothing to prevent the adoption of a lower frequency in the then early stages, &c.," he assumes a familiarity with American conditions in 1888-1889. The statements he makes show conclusively that he does not, and did not, possess this familiarity. The great demand for an alternating single-phase motor in 1888-1889, and even now, is for one which will go upon the existing lines distributing alternating-currents of 125 to 130 frequency. The actual fact was that in America up to 1889 these frequencies had been largely introduced, and the desire for uniformity has continued the practice even to the present, when we know much better than we did then what the practical differences in the use of high or low frequencies are. There is now, indeed, a tendency in America to come down to lower frequencies, but it is as yet little more than a tendency. Let us suppose that we had in our possession on sale a few hundred of Mr. Brown's modification of the single-phase motor here in America, and of all sizes and capacities, and then put the question, could we sell them to run on existing systems practically, economically, and satisfactorily? and the bearing of the high-frequency question, even to-day, in spite of tendencies, will be emphasised in the answer.—Yours, &c.,

ELIHU THOMSON.

GAS POWER FOR ELECTRIC LIGHTING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I should like, through the medium of your columns, to call the attention of gas-engine manufacturers and others interested in gas power for electric lighting to certain points which appear to be neglected. I am a believer in the future of gas engines for central station electric lighting, the gas to be produced by Dowson's generator, or some similar apparatus.

Without expressing any opinion on the merits of the various systems of electrical distribution, I may safely say that there are many places, especially the smaller provincial towns, where the alternating system is the only one that can be used with success. It is also well recognised that the parallel running of alternators is a point of the greatest importance.

As consulting engineer to two central stations about to be put down, I am endeavouring to procure a type of gas engine which will be steady enough to work alternators in "parallel," even at light loads.

For this purpose the single-cylinder, single-acting type of engine, working on the Otto cycle, governed by cutting-out explosions, is manifestly unsuitable, and gas-engine manufacturers who are simply relying on high speeds and heavy fly-wheels are clearly not on the right road to success. It is possible in central stations of small size to arrange for the mechanical coupling of the alternators, but this would probably be found impracticable on a large scale. For working alternators, even of the best type, in parallel it is certainly necessary that each engine should have at least two impulses per revolution.

Totally regardless of this, most of the chief manufacturers advertise their single-cylinder, single-acting engines as perfect for dynamo driving, thereby utterly ignoring that system of electrical distribution which is more used than any other, and which these so-called perfect engines are totally incapable of driving successfully. There is but little difficulty with direct-current dynamos helped by accumulators, but gas-engine manufacturers are very blind to their own interests if they continue to ignore alternating-current working, as they are at present doing.

Even for direct currents, high speeds and heavy fly-wheels are a disadvantage, for they mean excessive wear and tear and liability to break-down, which should be avoided if possible. Could the difficulty of stuffing boxes be overcome (and one firm appears to have succeeded in this), the adding of an extra single-acting cylinder tandem fashion would give one impulse per revolution, and would double the power of an engine without increasing the size of its connecting rod, main bearings and other parts in front of the cylinders. Two such tandem engines coupled would give two impulses per revolution. A twin-cylinder, double-acting engine gives two impulses per revolution, as would also a tandem engine with double-acting cylinders. This latter type would have great advantages. The connecting rod, main bearings, &c., need not be larger than those for an ordinary engine one quarter the size, so the engine should be a cheap one in capital cost, and should have a high mechanical efficiency.

This difficulty of stuffing boxes seems to me capable of solution by passing cooling water through the piston rod. I can imagine several ways in which this could be arranged. It is certainly in the direction of quadrupling the number of impulses that manufacturers should work, if they wish their

Digitized by Google

engines ever to be used in alternating-current central stations. Not only this, but governing down to at least half load must be performed by varying the power of explosions, and not by cutting them out altogether.

Trusting that you will kindly insert the above,—Yours, &c.,

J. A. McMULLEN, M.I.E.E.

London, N.W., April 26, 1893.

CONCENTRIC WIRING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the present letter I propose to deal with the objections raised by you to some points connected with the use of grooved boarding, or casing (if the term be preferred), that were raised in my article which was printed in *The Electrician* of the 7th inst.

In the first place I would like to enter a protest against the assumption, which I believe is contained in your Note, that articles in technical journals should only contain what does not happen to be common knowledge to those few engineers who stand in the front rank of their profession. The great majority of writers on technical subjects spoil their work and seriously detract from its usefulness, in some cases even rendering their writings absolutely worthless to all except a favoured few, because they have before them when writing not those to whom their knowledge and experience would be of immense value, those who have not the opportunity of acquiring it for themselves, but their own *confrères*, their own rivals—those who know as much about the matter as they do themselves.

Technical literature, if it is to fulfil its proper function, and whether it be in the form of books, of articles in technical journals, or of Papers read before scientific societies should be written primarily for those who do not know, not for those who do know the subject well. Of what use is technical literature unless this rule is observed.

In the present case you very truly remark that the best firms do not use soft wood, &c. That is to say, you mean, if I understand you aright, that those who understand their work thoroughly do not commit certain faults that were condemned in my article. But the article was not written for the best firms. The writer would not think of attempting to teach those who understand the subject quite as well as he does himself. It was written for those who do not understand, and who do bad work in consequence. Electrical engineers who do understand their work may chafe as much as they please against orders going to men who do not understand their work; but the orders will go there all the same, and the major portion of them, simply because the prices asked will always be less. In the matter under discussion, too, it is well known that as soon as the electric-light mains are laid in a town every ironmonger, bell-hanger, plumber, and general jobber dubs himself an electrical engineer, lays himself out to take orders and, having plenty of time, often not too scrupulous a tongue, and putting the figure low, he gets them.

Now, the question is, What is the best course to adopt with regard to these? They are only birds of passage, though they rob old-standing businesses of a good deal of work. It is useless to warn intending employers. They rarely see the technical journals, and if *bonâ fide* contractors do go out of their way to warn them, their action is looked upon as due to trade jealousy, because the prices are lower. More than that, the ordinary buyer will often think that the *bonâ fide* contractor is making a deliberate attempt to swindle him. In any case, it is bad form at best to insinuate that other people's work is bad, and it is not a wise course to pursue.

As the irregular contractor cannot be kept out, is it not the next best thing to give him an opportunity of knowing something of the work he is undertaking, so that there may be fewer chances of his doing his work badly?

It is not much that can be done, even by the ablest writer, in this direction; but every little that can be done is so much gain. Bad as it is for the irregular contractor to get work away from those who have spent time and money in mastering their business, the evil is very small compared to the deterrent result produced by bad work. Next to securing a contract himself, the writer always likes to see it go into the hands of a firm that will carry it out well. There are also another class of readers to whom information of the kind contained in the writer's article should be of service, viz., those who actually have the execution of the work. Young engineers and workmen often have ideas of their own which they are apt to act upon, and which are sometimes not in accordance with the wishes of their employers. Now, as to the casing itself. Whether hard or soft wood is used moisture will collect in the pores unless these are previously filled with some other substance; and of possible substances shellac is the best, except in a few special cases. Paint or pinotting should not be used, because they will not thoroughly fill up the pores, and because they contain metallic bases which will be deposited by the leakage current.

It may seem to strain matters to say that hard woods will hold moisture; but when we remember the trouble that arose in the early days of the Leclanché battery, from the salts creeping up the pores of the carbon plate and attacking the lead cap, until the pores of the tops of the plates were filled with paraffin wax before being capped, we should not be surprised.

Next, no substance that is used for the insulation of electric light cables will withstand the continuous presence of moisture. Gutta-percha stands wet better than any other substance, but gutta-percha has long been tabooed for electric lighting cables, and even gutta-percha gives way if there is much moisture present and the insulator is thin. Of course, the thicker the coating of indiarubber, the longer it will resist the action of moisture; but the question is only one of time after all, and it is less expensive to exclude the moisture than to increase the thickness of the rubber covering.

It need hardly be mentioned, too, that even in the very best-built houses moisture is very often present during wet seasons; while in the modern villa, which will form a large portion of the work of the future of this kind, damp is too often always *en évidence*.

Now, my point is that unless the pores of the wood-casing are filled up with an insulating substance, the wood acts like a sponge, collecting moisture wherever it is present and presenting it to the insulating covering of the wire proper in the manner calculated to do the greatest amount of damage. It should not be forgotten, also, that the leakage current aids the action of the moisture very materially and adds to the trouble.

You ask, if moisture is to be excluded why not go back to the impregnated jute covering, and you also ask, surely wood-casing is only intended for mechanical protection? Both of these queries should be answered in the affirmative. Where jute covering is permissible as an additional protection, outside of the regular insulation, the writer prefers it very much to grooved boarding, and his experience is that if plenty of jute be used a very much better result is obtained than is possible with wood-casing.

But in many cases jute is not permissible. In domestic work, for instance, it cannot be used; and there may also be places where it is more convenient to use casing than a covering of jute. In either case my view is that the moisture should be prevented from collecting.

Your objections with reference to bad joints and the arrangement of joints will be met by the remarks that have been given above. It is not those who practice the best methods for which the article was written, but those who do not, and whose failure to do so may possibly have been due to want of knowledge or experience.

The writer will make a few remarks in reply to Mr. Sam Mavor's letter in the current number of *The Electrician*, and will hope to deal with the question of "earthing" electric light circuits in another article.

My view is that cable makers cannot put either lead or armour outside of the insulation of the cable without danger of damaging the latter. It does not follow that the cable breaks down at once. Often no known test will disclose the incipient fault; but in course of time the leakage current finds out places where the insulation has been strained, and gradually breaks it down, a spark passing across and destroying a considerable length of the cable.

Digitized by Google

The cable I mentioned, which caused a fire on board ship, formed part of an electric-lighting system in which the body of the ship formed the return circuit, the outer armour of the cable being in contact with it everywhere. Mr. Mavor also asks whether my advice to make all connections large and in sight is not a confession of weakness, and he asks further, why not close the whole thing in, as suggested in Mr. Mavor's first communication. My reply is that in my experience you cannot safely close the whole thing in. Moisture will find its way through the finest capillary space, and, as is well known, capillary attraction defies gravity. If you can weld the adjacent portions of metal together, beneath which the joint is enclosed, you can keep out moisture, but in welding you will destroy the insulation.—Yours, &c., SYDNEY F. WALKER.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

TENDERS INVITED.—The Corporation of Clonmel, Ireland, invite tenders for lighting the streets of the town and the Town Hall by electricity. Street lighting areas represent about 6¾ miles, and ample water-power can be obtained upon reasonable terms within easy distance of the town. Some further particulars will be found elsewhere, and tenders must be sent in to Mr. John F. O'Brien, Town Clerk, by the 25th inst.

——— The Board of Governors of the Killarney District Lunatic Asylum ask for estimates for the installation and supply of electric light to the asylum, the number of existing gas-lights exceeding 400. The Board will discuss these estimates at their meeting on May 18th. Communications have to be addressed to Dr. Griffin, the resident medical superintendent.

——— The Richmond Main Sewerage Board invite tenders for providing and fixing the necessary apparatus for lighting their works at Mortlake by electricity. Some particulars will be found in our advertisement columns, and all other information can be obtained of Mr. William Fairley, resident engineer, Main Drainage Works, Mortlake, S.W. Tenders must be sent in to Mr. J. Leslie G. Powell, Clerk to the Board, 13, The Green, Richmond, Surrey, on or before the 23rd inst.

——— The Council of the Borough of Brighton invite tenders for the supply and erection at their electricity works, North-road, of the central station switchboard and apparatus. Specifications can be obtained on application to the Town Clerk's office, Town Hall, Brighton. Tenders must be sent in to Mr. J. Tilstone, Town Clerk, before 10 a.m. on Monday, the 15th inst.

——— Tuesday next is the last date for sending in tenders for the wiring and supply of electric-light fittings for the central station of the Borough of Huddersfield. Tenders should be sent in to Mr. A. B. Mountain, Borough Electrical Engineer, Gasworks-street, Huddersfield.

——— The Manchester Corporation invite tenders for the supply of dynamos, engines, switchboards, cables, and lamps complete for the stores and chill rooms about to be erected in Elm-street, adjoining the abattoirs. Specifications, &c., may be obtained on application at the office of Mr. M. C. Bannister, 29, Princess-street, Manchester; and tenders must be in by the 23rd inst.

——— The Gas Committee of the County Borough of Salford require tenders for the erection of the buildings for their electric lighting station. These tenders must be in before 5 p.m. on Thursday, the 11th inst.

——— The Municipality of Péruwelz, Belgium, invite tenders for the concession for lighting the town by electricity. All information can be obtained from the Communal Secretary, and tenders will be opened at 2 p.m. on June 12th.

TENDERS ACCEPTED.—The Gas Committee of the Aberdeen Town Council have submitted the tenders received for the works and plant for the electric lighting scheme, and the following tenders have been accepted :—

Electric Construction Corporation (Limited), engines, dynamos, &c.	£5,044
Messrs. Simmons and Co., switch boards	990
Babcock and Wilcox (Limited), boilers	1,494
Electrical Power Storage Company (Limited), batteries	760
Messrs. Bolton and Sons, copper strip (about 30 tons)	1,820
The Callender Company, cables	1,532
British Insulated Wire Company (Limited), pilot wires	190
Messrs. Doulton and Co., insulators	177
Messrs. M'Kinnon and Co. (Aberdeen), iron roofs	410
Messrs. M'Kinnon and Co. (Aberdeen), iron battery stands	56

The building work has been given to local firms. The total contracts, including the buildings, amount to £17,918.

——— The tender of Messrs. Siemens Bros. and Co. has been accepted by the Derby Corporation for laying the mains, &c., with all accessories, for their electric lighting scheme.

——— The Gas and Electric Light Committee of the Burton Town Council have recommended the acceptance of the tender of Messrs. John Fowler and Co. of Leeds (in conjunction with Messrs. Hammond and Co. for the electric-lighting works). In moving the adoption of the report, which was subsequently carried, Alderman Lowe confidently anticipated that by Christmas the current would be obtainable for lighting purposes.

MICA.—Messrs. Wiggins and Sons have again secured the Admiralty contract for the supply of mica to that department.

SALE BY AUCTION.—Mr. Thomson, auctioneer, will sell at Pulrose Crossing, near Douglas, to-morrow (Saturday) unless previously sold in one lot, a quantity of electrical plant and apparatus, and also a complete electric lighting installation, consisting of a Robey engine, Crompton dynamo, and arc lamps, regulating apparatus, &c., which have recently been in use at the Panorama Buildings, Douglas, Isle of Man.

SALE BY TENDER.—Owing to the dissolution of partnership of Messrs. F. Reid, Nichol and Co., tenders will be received by Mr. Thomas Bowden, of 42, Mosley-street, Newcastle-on-Tyne, by noon on the 17th inst. for the stock of electric light wires, fittings, arc lamps, carbons, lightning conductors and fittings, bells and telephones, forming the stock of the dissolved firm. This stock will be on view at Forth House, Bewick-street, Newcastle-on-Tyne, from May 10th to 13th inclusive. Further particulars can be obtained of Messrs. Thomas Bowden and Nephew, chartered accountants, Newcastle-on-Tyne.

APPOINTMENTS VACANT.—The Corporation of Bristol require an assistant engineer for their Central Station at a salary of £2. 10s. per week. Further particulars will be found elsewhere, and applications must be sent to the Town Clerk, Electricity Department, 51, Prince-street, Bristol, by the 16th inst.

——— To-morrow (Saturday) is the last day for sending in applications for the appointment of resident electrical engineer for the borough of Wolverhampton. Applications should be sent in to Mr. Horatio Brevitt, Town Clerk.

PERSONAL.—Mr. R. H. Claxton, who has been for many years manager of the Liverpool district of the National Telephone Company, has been promoted to be superintendent of the North-Western system of the Company, and will have the control of Manchester and other large towns.

——— Mr. Robert Gilmour, who has been telephone superintendent at Aberdeen for some years past, has been promoted by the National Telephone Company to be superintendent of Dundee. Mr. Gilmour is succeeded at Aberdeen by Mr. Brown, of the Mid-Lanark or Hamilton telephone district.

BANKRUPTCY.—The total debts of Edward J. Bayly, lately carrying on business at Liverpool as an electrical engineer, have been returned at £152. 15s. 6d.

IRON AND METAL TRADES PENSION FUND.—The celebration of the jubilee of this fund will take place at the Guildhall, under the presidency of the Prince of Wales, on June 21st, and not May 11th, as previously announced.

TELEPHONE CABLES.—A telephone cable about 1¼ miles in length has been laid across the River Tay, at the point below Dundee, by Messrs. T. Smith, of Messrs. W. T. Henley's Telegraph Works Company (Limited), by which firm the cable was made for the National Telephone Company (Limited).

INDESTRUCTIBLE IGNITION TUBES.—The Indestructible Ignition Tube Syndicate (Limited), owners of Wellington's patents for gas and oil engines, &c., send us a sample of their ignition tubes, for which they claim many advantages—including endurance, instantaneous heating, ease of starting, and simplicity of fitting. The particulars issued show that the tubes are in use in a number of large business houses, and that they are being supplied to all the principal gas-engine builders, including Crossley Bros. and Tangyes. The tube appears to be made of a white porous porcelain.

WATERHOUSE ARC LAMP.—The Waterhouse Electrical Manufacturing Company send us some printed particulars and prices of the Waterhouse arc lamp. Copies of this list can be obtained from the Company's offices at 33, Old Broad-street, E.C., or from the works, 67, Southwark Bridge-road, S.E.

ANTWERP EXHIBITION.—Further printed particulars are to hand relating to the Exhibition to be held at Antwerp on May 5, 1894. Special competitions, meetings, and conferences will be held during the Exhibition, which has received the special patronage of the King of the Belgians and the official support of the governing authorities of the city of Antwerp. The Committee of the Exhibi-

Digitized by Google

tion consists of the leading Belgian commercial houses. It is to be regretted that a lottery is to form a feature of the Exhibition, the prizes in which are to be purchased from exhibitors exclusively.

BRIDLINGTON.—The Local Board have resolved to expend £340 for a Crossley's "Otto" gas engine for supplying the motive-power for lighting Prince's Parade with electricity.

BRISTOL.—Mr. Preece, before the Electric Light Committee of the Bristol Corporation, stated that most satisfactory progress was being made by the contractors, and that the light would be supplied in August.

BLACKPOOL.—Dated April 24th, Mr. William Chew, electrical engineer to the borough of Blackpool, has forwarded a report of the working of the electric light stations, Nos. 1 and 2, to the Markets and Gas Committee. The report states that the manufacturing appliances have been maintained in good condition, the chief items of renewals consisting of switches, armatures, lamps, and lanterns. The distributing plant is in need of repair for the coming year. Working expenses have not reached the estimated cost, showing a surplus of £70. Taking the returns for 1892 of the nine leading London and Provincial electric-lighting concerns, Mr. Chew puts the highest cost for working at 8·92d. per unit, the lowest 3·43d., or an average of 4·81d., with the addition of dividend items. The net cost of the Blackpool supply was 3·46d. per unit for the current supplied to the public lamps. Careful investigation had proved that the demand for the light in June is about one-third of that in December. The number of private lights in use was 18 per cent. of the total, but private consumption represented only 5·25 per cent. of the year's output.

CHAGFORD.—The proprietors of the Chagford Gas Works have recently held an exhibition of gas appliances, with special reference to the advantages of cooking by gas. A competing exhibition is, we understand, shortly to be held, to show the greater advantages to be obtained by cooking by electricity.

CITY LIGHTING.—The City of London Electric Lighting Company give notice that application is being made to Parliament in the present session for a Bill to alter and amend the provisions of the City of London Electric Lighting Orders, 1890 and 1891, with respect to the keeping of accounts and setting aside all depreciations and reserve funds, and to provide that the undertakings covered by the various Orders shall be deemed to be one undertaking. The Bill also asks for the exemption of any building used by the City of London Company for the generation of energy from the operation of the Metropolitan Building Act of 1855, &c. Copies of the Bill were deposited in the Private Bill Office on the 1st inst. Mr. Sydney Morse is solicitor for the Bill.

COATBRIDGE.—The Scottish House-to-House Electric Lighting Company (Limited) have commenced laying the mains for the installation at Coatbridge, and promise the Town Council that current shall be supplied in about three months from the 1st inst. The Lighting Committee have under consideration the type of lamps and fittings to be supplied for public lighting.

DERBY.—As announced on the previous page, Messrs. Siemens Bros. and Co.'s tender for the laying of the mains, and supply of accessories, in connection with the electric-lighting scheme of the Corporation, has been accepted, and considerable progress has been made during the last few months with the works and buildings. Messrs. Bramwell and Harris, the consulting engineers, report that the light will be ready for supply by about the middle of July next. Arrangements have already been entered into for introducing the electric light into the Free Library and Reading Rooms.

DORCHESTER.—Arrangements are being made for lighting the town of Dorchester by electricity.

DUNDEE.—The Finance Committee of the Gas Commission have received permission from the Secretary of State for Scotland to borrow a further £1,000 for the purposes of works under the Dundee Electric Lighting Order of 1890, making the total amount borrowed under this Order £30,000. In conveying this sanction it was pointed out that on the further borrowing powers now conferred being exercised, an additional sum of not less than £175 should be carried annually to the sinking fund for paying off the money raised for electric lighting purposes. The money has been borrowed at 3¼ per cent. for a period of four years.

EXETER.—The Devon Standing Joint Committee having discussed the advisability of introducing the electric light into the whole of their offices, it was decided to consult the electrical engineer of the local electric lighting company, and make a report at the committee's next meeting. It was, we learn, ultimately decided to light the county clerk's offices.

GLASGOW.—A specimen of the new tramway car, which is to be adopted by the Glasgow Corporation on taking over the tramways in July, 1894, has recently been submitted to the Council for inspection. It is to be lighted by two electric lamps, and other improvements in tramway car arrangements are to be adopted. We understand the Brush Company are manufacturing the cars.

HANLEY.—On Tuesday last the Town Council discussed the advisability of substituting 30 1,200-c.p. arc lamps, in lieu of the 2,000-c.p. lamps originally specified for street lighting, to take the place of the large gas lamps at present used in the principal thoroughfares; it was also decided that the mains for incandescent lighting be laid down at the same time as the arc-light mains. An electrical engineer, to have charge of the construction of the works at a salary of £200 per annum, is to be appointed, the selected candidate to devote the whole of his time to the duties.

HOTEL LIGHTING.—Mr. W. Cornhill, Kinloch Arms Hotel, Carnoustie, Scotland, has had the electric light installed throughout his hotel. The light is giving great satisfaction. The plant consists of a Mather and Platt dynamo, and a 4½ H.P. engine. The work has been done by Mr. J. Anderson, of Carnoustie.

ISLE OF WIGHT.—The West Cowes Local Board have received a letter from the Secretary of the Isle of Wight Electric Lighting Company, in which he refers to the want of public interest shown by the residents of Cowes in the proposed electric lighting works, and the difficulty the Company has experienced in securing the necessary capital. Under these circumstances, although the Company had a considerable amount subscribed, it would not justify them (in the opinion of the Directors) in going forward without further financial assistance. The Directors, therefore, left it to the Local Board to take such steps as they thought fit, and hoped the Board would allow the matter to remain in abeyance for a short time longer to enable them to make another effort to raise the necessary capital. The matter was referred to the Lighting Committee.

LARNE.—The Town Commission have had under consideration an offer from the receiver and manager of the firm of Messrs. J. E. H. Gordon and Co. (Limited), relative to the purchase of the electric light installation at Larne for the sum of £8,000, payable in cash or in town stock. It was stated that the working expenses of the installation amounted to about £300 per annum, and that the income was in excess of that figure. After some discussion a resolution declining to purchase was carried.

LIVERPOOL.—The *Liverpool Mercury* of the 29th ult. contains an account of a visit to the new switch room of the National Telephone Company of Liverpool.

MANCHESTER.—A considerable addition is being made to the arc-light installation at the Zoological Gardens, Bell View, Manchester. The arc lamps are of Richardson's differential clockwork type, lighthouse pattern. Mr. A. W. Richardson, of Patricroft, has supplied the whole of the plant from the first.

MIDDLESBOROUGH.—In reply to requests from several users for permission to carry electric light wires overhead, the Middlesborough Corporation have decided that on no consideration whatever will overhead electric light wires be allowed in the town.

NEWCASTLE.—The report of their architect to the Cox Lodge Asylum Committee was discussed at the last meeting, and the estimate of cost for lighting the Asylum either by gas or electricity was put at an equal figure. The electric light will, of course, be selected. The question of motive-power is for the present deferred.

NORWICH.—The extensive premises occupied as a boot store by Messrs. Stead and Simpson, known as St. Andrew's-chambers, have been fitted throughout for the electric light, the current being supplied by the Norwich Electricity Company, under the superintendence of Mr. Pretty, the Company's engineer.

OSWESTRY.—Further progress has been made in the establishment of a local electric light and power company for Oswestry, and there is now no doubt that the project will be carried out.

SOUTHAMPTON.—About 400 electric lamps are fitted at and about the new Empress Dock, and there are already 20 3,000-c.p. arc lamps, and nearly all the mains are laid. Two additional 3,000-c.p. arcs have been erected on that part of the quay used by the American liners, and the whole of the installation is approaching completion. One of the sets of combined engine and dynamos has been running for some time past, and is giving great satisfaction; two further sets will be in working order by the end of May. Messrs. Crompton and Co. (Limited) are the contractors for the work, which is being done under the supervision of Mr. B. H. Jenkinson.——A sub-committee, appointed to inspect the electric cranes which are being supplied to the Docks, have, through the Mayor, expressed to Messrs. Statter and Co. and to Messrs. Stothert and Pitt their gratification at the success of these cranes. No. 1 of which is now completed, No. 2 being well in hand. The Committee saw the crane at work, and it will be fitted at Southampton next week.

SOUTH SHIELDS.—The Corporation have decided to carry out the electric lighting scheme for which they obtained an order about two years ago. A report has been presented by Mr. E. J.

Digitized by Google

Jennings, in which he estimates that plant for the supply of 6,000 lamps would be sufficient for lighting the streets in the compulsory area, but that provision will have to be made for a probable extension necessitating about 2,000 additional lights. He estimates the cost of the necessary works at £14,000, and that 5¾d. per unit would be a sufficient charge to pay interest and working expenses. It will be necessary for an extension of time to be applied for by the Corporation in order to carry out the details of the scheme.

WEST HAM.—With regard to the report presented by the Works Committee recommending the Council to proceed to put in force the Provisional Order obtained in June last, the Council have decided not to adopt the report, and have referred it back to the Committee for consideration, with a view to a scheme being prepared for the establishment of a central station.

WORCESTER.—At the last meeting of the Guardians a discussion arose on the decision of the Building Committee to postpone the introduction of the electric light into the new workhouse. It was the opinion of a number of the members present that electric light for the public buildings was very desirable, and that the matter should not be shelved. In the result the report of the Building Committee was, however, adopted.

COMPANIES' MEETINGS AND REPORTS.

Brazilian Submarine Telegraph Company (Limited).

The thirty-ninth ordinary general meeting of the shareholders of this Company was held at Winchester House, Old Broad-street, London, on Wednesday, May 3, 1893, the Hon W. St. John Brodrick, M.P., presiding.

The SECRETARY (Mr. Richard Collett) read the notice convening the meeting and the minutes of the thirty-eighth ordinary general meeting held on October 19th last. The report of the Directors was taken as read.

The CHAIRMAN: I will now proceed to make a few remarks in moving the adoption of the report and accounts. Before doing so, however, I cannot help expressing to you the regret which we feel that our Chairman, Sir James Anderson, is unable to be here to meet you to-day. I am sure that all those who know that Sir James Anderson has been suffering for some weeks from very severe illness will greatly regret his absence. We are all aware of the great advantage which this Company, from its formation to the present day, has gained by the experience and attention which Sir James Anderson has brought to bear on its business, greatly to the advantage of the Company and the help of the Board. As regards the report and accounts, our revenue for last half-year exceeded the revenue for the preceding half-year by a little over £2,000. That increase, however, is rather apparent than real, because a certain sum came into the accounts of the last half-year which had been held in suspense in the preceding half-year, and which would have altered the balance. Comparing our revenue of December, 1892, with the revenue received in the half-year ended December, 1891, we have a decrease of £13,000; but, on the other hand, we have a decreased expenditure this half-year of something like £5,000, although we have had to meet some unusual calls in connection with our staff quarters at St. Vincent. In the previous half-year we had to meet other calls in connection with the duplexing of cables and repairs, which have not occurred to the same extent this half-year. I should like to say a word to explain the expenditure at St. Vincent. We have had to put on a considerable increase of staff there, in consequence of the large amount of business to be transacted, and the establishment of a day and night service, as well as the increase of business which comes from the West Coast of Africa and the Cape Colonies. That has necessitated an extension to our station, the expense of which has fallen, to a considerable extent on the half-year under review. In addition to that, the Board, after carefully considering the subject, came to the conclusion that it would be necessary to erect tanks and tank sheds and machinery at St. Vincent for keeping spare cable there, and the shareholders will be able to appreciate the foresight which dictated that operation when they consider the instance of the repair which, I am glad to be able to announce, has just been executed in connection with the removal of a fault in cable No. 2, near Pernambuco. We chartered the nearest and the most easily available telegraph ship to repair it. She was at the time on the west coast of Africa. She called at St. Vincent, and there took in the necessary cable, and proceeded direct to the scene of the fault, which was removed on the 28th of last month, and she was able to return without even touching at South America. The economy created by having the cable ready at St. Vincent, so that the ship had not to come to England for it, has been very considerable, and has already justified the expenditure which we were put to at St. Vincent, which in the half year came to £2,600. Since the last meeting other repairs have been executed in the No. 1 cable from St. Vincent to Pernambuco, and in the No. 1 cable from St. Vincent to Madeira, and we have laid down very heavy cable for shore ends at Madeira. It is the hope of the Board that the cable now laid down will be found sufficiently strong to resist the very heavy surf which in certain gales besets the coast of Madeira. The shareholders will be glad to know something with respect to the opposition we have had from the South American Cable Company. You are aware that a Company has been established connecting Senegal with South America, which may be considered to be in opposition with this line. The South American Cable Company opened on October 5th last and operated until December 27th. On December 27th a break occurred in their cable, which was totally interrupted until February 9th. Recently notice has been given by the South American Cable Company of a decrease of rates, to take effect from April 1st last. After consulting the Western and Brazilian Company, the Board decided to adopt similar rates to those of the South American Cable Company, and as the object of that Company is to take our traffic, the Board will, if necessary, continue in conjunction with our allies to reduce rates to the level notified by the opposition. We have very carefully considered the effects of this opposition and of the working hitherto, and the experience gained of this working does not make the Board greatly fear the loss that may be incurred by this competition. There is one subject which is extraneous to the usual business of the meeting, on which I have to address a word or two to you. We propose to ask your leave to establish a fund for the pension and superannuation of *employés* of the Company. Gentlemen, you will be aware that the Eastern Company, the Eastern and South African Company, and the Eastern Extension Company have all adopted superannuation schemes and a pension scheme recently on the same basis. Their proposal has been—and we intend to ask the shareholders to adopt the same—that the pension fund should be established by a contribution of 2½ per cent. from their salaries by every member of the staff under a certain period of service, and that the Company should then add 2½ per cent. to meet that contribution. We have reason to know that the arrangement so made will be satisfactory to the staff, and will also provide, after many years of service, an adequate pension to those employed. The superannuation scheme is a little different. That has to do with the older members of the staff, who, if they were now put on a pension scheme, would not by their contributions supply a sufficient amount to provide in any way for their old age. There are two objects to be achieved in respect to this contribution. In the first place, it will be remembered that we are working with the Eastern Telegraph Company, that we have a joint telegraph station with them at Lisbon and Carcavellos, and a joint training establishment; and it will be obvious to every one that it would be undesirable, and might cause the loss to this Company of really good and useful men, if we were in a less favoured position than the Companies with which we have working agreements. The other object necessary to dwell upon is that we have to start a pension scheme not merely following what has become the practice of our colleagues—if I may so call them—of the telegraph world, but following the general principle which has been adopted by all public establishments and in the public service in the present day. Great schemes for superannuation and pension have been adopted quite recently in many of the largest public establishments, and it is not merely desirable, but it is a distinct advantage to the Company that we should do the same. We should have something of a hold on valuable men, so that when they have given us a certain period of service they should not be induced to transfer their abilities elsewhere, but should have the certainty of their contribution and our contribution to the pension scheme to induce them to remain in our service. Now, the shareholders will naturally ask me what is going to be the expense of this scheme. That matter we have carefully considered, and have had reported on by actuaries of eminence. The shareholders voted on the 20th of May, 1881, towards an insurance fund—a sum not to exceed £800 a year. We have never exceeded that amount, and it will in the future still suffice for the payment towards the superannuation of the older members of the staff proposed under this scheme. In addition to that, for the younger members of the staff we propose to meet their contribution by a contribution of 2½ per cent. on our own part, and that will cost, at the present rate of the salaries, about £500 a year. I do not think that the shareholders will feel, having regard to the nature of the occupation, the number of those employed, the fact that a great deal of our service is tropical, and the very extended operations of the Company, with its large revenue, that £500 is an undue amount to pay for the advantages which I have just described; and I am quite certain, after the fullest consideration, that we shall find it a prudent and economical operation, and in the best interests of the Company. I need not say anything more except that the shareholders will be able to gather from the report which we have submitted, and from the accounts, that the position of the Company continues to be very strong, and that we have a substantial reserve fund. Our property is in a stable condition in the market, our shares are at a premium, and remain firm, and the policy which has been pursued is, I think, the best guarantee of security for adequate dividends in the future. I need hardly say that the Directors will do everything in their power to ensure a continuance of their security. I now propose the following resolution:—

"*That the report of the Directors and the accounts to December 31, 1892, now submitted, be approved and adopted.*"

Sir HENRY D. GOOCH, Bart., seconded the motion.

Mr. W. GRIFFITH said he desired to endorse the policy of the Directors as to the pension and superannuation funds. They had already adopted the principle of the proposal in respect to their older servants, and they were, therefore, merely extending the principle. He thought they must all admit the advisability of having in the service of the Company gentlemen who were contented and who were likely to remain with them. In looking over the accounts he had been rather struck at the large amount put to reserve fund—£35,000—in view of the fact that their system was in such good order that there seemed very little likelihood of their being called upon to lay any other cable at present. Moreover, they had already paid off a very large portion of their debentures, and they would be able later on to raise money easily. The state of their property and the small mortgage on it rendered it less necessary for them to have so large a reserve fund, and he thought that the shareholders would be only too happy if the Directors would consider the advisability of increasing their dividends, more especially as, according to what the Chairman himself had said, the prospects of the Company

Digitized by Google

were so good. Of course, what he had said was by way of suggestion rather than anything else.

The CHAIRMAN: Mr. Griffith has called attention to a very well-worn subject, that of the reserve fund. I am glad, in the first place, that he approves the superannuation fund, of which, as he said, the principle has already been established. No doubt the reserve fund stands at a very high figure, but I would venture to remind you that our No. 1 cable—although, as far as we know, it is in excellent condition—is between nineteen and twenty years old, and we must prepare ourselves some day for the renewal of that cable. In addition to that we have now to meet some extra charges in the present half-year for repairs of cables. We have consequently thought it desirable and prudent to recommend you to put to the reserve fund the sum mentioned, but I need hardly say that if at the close of the year we find ourselves in a position to pay more to the shareholders, no one will be more glad than the Directors to do anything that is prudent. However, I really think that the policy we have adopted in respect to the reserve fund has had a great deal to do with strengthening our hands against competition, and in preserving our shares in the satisfactory position which they now stand at in the market.

Mr. NEWMAN said he quite agreed with all the Chairman had said as to the reserve fund, which he thought could not be too large. He had always advocated that principle from the beginning, for if they had a large reserve fund they would always be independent of opposition. He hoped the Directors would continue to add to the reserve fund year by year.

The CHAIRMAN then put the resolution to the meeting, and it was carried unanimously. He afterwards proposed—

"*That the report of Messrs. Neison and Schooling, of the Institute of Actuaries, relative to the establishment of staff pension and superannuation funds having been submitted to the meeting, the Directors be and they are hereby authorised to cause such deed or deeds or other documents to be prepared as they may consider necessary for carrying out the scheme embodied in the said report, with such alterations and modifications, if any, as may be approved by the Directors.*"

That report is on the table, and it is a lengthy document, but I have given you the effect of it as regards finance. I thought that the shareholder would prefer not to be troubled with a long disquisition on the report, but, of course, any shareholder can see it at any moment, if he desires to do so at the office.

Mr. JOHN NEWTON said it had been suggested that the seconding of the resolution would come better from the shareholders' side of the table than from the other side. He therefore desired to second it as one who had benefited considerably in a small way from his investment in telegraph companies through the exertions of their staffs. He was confident that shareholders in a company like theirs would be glad to support, and to support cordially, such a scheme; and he was especially glad to see that the interests of the older members of the staff were not overlooked. It was to them, owing to their early labours, that the shareholders were considerably indebted.

The CHAIRMAN then put the motion, and having declared it carried unanimously, added that that concluded their business that day.

Mr. NEWTON proposed a vote of thanks to the Chairman and Directors for their services. In moving the resolution on the present occasion he thought that they ought to express their great regret at the serious illness of Sir James Anderson. He trusted that their Chairman might soon recover, and that the shareholders might again see his pleasant face among them. (Hear, hear.)

Mr. GRIFFITH seconded the motion. They were in a very prosperous state, and were greatly indebted to their Directors for this. He also re-echoed the wish expressed by Mr. Newton regarding Sir James Anderson. Perhaps the Directors would convey to him their expression of condolence.

The resolution was carried unanimously.

The CHAIRMAN: Mr. Newton and gentlemen, on behalf of my colleagues and myself, I thank you very much for your kind expression of confidence. I can assure you that we shall do everything in our power to preserve the Company in its present efficient and substantial condition.

The proceedings then terminated.

Indo-European Telegraph Company (Limited).

The twenty-sixth ordinary general meeting of the members of this Company was held at Winchester House, Old Broad-street, on Friday last, under the presidency of Mr. J. Herbert Tritton.

The MANAGING DIRECTOR (Mr. W. Andrews) having read the notice calling the meeting,

The CHAIRMAN said: I beg to move,

"*That the report and accounts now submitted be received and adopted and that a dividend be and is hereby declared for the half-year ended December 31, 1892, of 17s. 6d. per share, making, with the interim dividend already paid, 6 per cent. for the year, and a bonus of 20s. per share, both free of income-tax, making in all 10 per cent. for the year.*"

Gentlemen, there is again very little to be said upon the report and accounts of our Company for the year 1892. It may, perhaps, be as well for me to direct your attention to the total of the expenses account under maintenance in the revenue account—£30,188. This apparently shows an increase, arising, however, from our having written down the cost of certain more or less obsolete plant and apparatus for which we thought the year offered a favourable occasion. This policy is merely a continuance of former measures in the same direction, only that the sum that had to be dealt with was rather larger. As a fact—and you will be glad to hear it—I may say that there is a slight reduction in the actual working expenses. There are increases under the heads of salaries and wages, and for station expenses, and travelling connected with the message department, and removals of clerks; and diminutions under other heads, which it is not worth while to refer to. The revenue in the aggregate shows an increase of about £700. Adding the amount brought over from last year of £5,983 to the gross revenue, amounting to £117,479, after deducting expenses, crediting £10,000 placed to the reserve, and after deducting the interim dividend, there remains a balance of £39,432 available. This, as you have heard from the resolution, and seen from the report, the Directors propose to apply by declaring a dividend for the last six months of 17s. 6d. per share, and a bonus of 20s. per share, both free of income tax, and to carry forward £7,557 to the credit of 1893. This is the practical outcome of the year's working, and I have no doubt you will agree that it is a very satisfactory outcome indeed. The gross receipts for Indian business are still below those of the year 1886, when the reduction took place in the tariff, although the number of words is greater. The fact appears to be that in an old-established country like India, there is a very different state of things to that pertaining in younger and rapidly-growing communities. There may be, and are, of course, fluctuations and periods of greater or lesser activity, but the rapid growth all round is wanting. On the other hand, the great reduction of rates made with Australia has had for result a very large augmentation of the number of words transmitted, and I think it is not too much to assume that if the reduced rates had been let alone, the former amount of revenue would have been recovered in a very few years. The Colonies, however, found it necessary, owing to circumstances that will be in the mind of every one, to take steps to diminish the losses that were being sustained, and an addition of 9d. per word was made to the lowered rate in order to get back not all the loss, but some of it. This small addition still left the rates very low for the enormous distance traversed. This Company hopes and believes that this small addition will by-and-by be knocked off again. The pause in the advance of the great Australian Colonies which we are now witnessing, however trying at the present moment the process may be, is salutary and even necessary. Our friends have to learn that the development of their immense territories and resources must be their first object, and that the adage of "Australia for the Australians," if persisted in, will be their ruin. They must encourage settlement on the land in order to develop their exports. They must ensure wisely-directed and not improvident expenditure, and they must re-establish by rigid economy that credit which will enable them eventually to take the lead in the commerce and production of the world. The working of the lines continues to be most satisfactory, as well in India as throughout the Indo-European system of the Indian Government and the Company. Shareholders should not in my judgment fail to remember that prosperous as the Company is, there are yet contingencies which must be reckoned with in estimating the position and future of the Company. I now move the resolution which I have already read.

Mr. H. WEAVER seconded the motion.

The CHAIRMAN said he would be happy to answer any question. If there were no questions to be asked he would put the resolution, which was carried unanimously.

Mr. Earle and Mr. Holland were re-elected as Directors, and Messrs. Kemp, Ford and Co. as auditors.

On the motion of Mr. G. VON CHAUVIN, seconded by Mr. STEPHENS, a vote of thanks to the Chairman and Directors was passed, and the proceedings terminated.

West Coast of America Telegraph Company (Limited).

The sixteenth ordinary general meeting of this Company was held on Tuesday last at Winchester House, E.C., Mr. J. Denison Pender (Chairman) presiding.

The SECRETARY (Mr. Fred. L. Robinson) read the notice convening the meeting, the report of the Directors and statement of accounts being taken as read.

The CHAIRMAN said: Gentlemen, in moving the adoption of the report and accounts for the year 1892 I will refer to some of the items in the accounts. The large decrease in the gross receipts of the Company is, as you are aware, owing to the fact of your cables and land lines having been practically isolated from the outside world, and the traffic almost wholly confined to local work, at reduced rates, consequent upon the competition of the American Company at Lima, Iquique, Valparaiso, and Santiago, our principal stations. The receipts have also been affected by the continued depreciation in the value of the currency. Turning to the other side of the accounts, your attention has been drawn in the report to the reduction in the gross expenditure of about £2,500, as compared with the previous year. This reduction is attributable to economies effected on the West Coast, and to the comparatively small outlay for maintenance of the cables and land lines, notwithstanding that this item includes the greater part of the cost of reconstructing the land lines between Valparaiso and Santiago, and the expenses connected with taking over new and more commodious premises at Valparaiso. During the past year the cables were only interrupted on two occasions. A fault appeared in the shore ends at Iquique in June, and the northern section between Mollendo and Lima was broken by an earthquake in November, the necessary repairs being in each case promptly effected by the repairing steamer "Retriever." The steamer is stationed at Callao, and is, I believe, kept up to the highest degree of efficiency. With regard to the extension of your cable to Talcahuano, which is one of the most important works carried out during the twelve months under review, this matter has received the earnest attention of the Board for some time past. Our customers on the West Coast want a more reliable service between Valparaiso and Concepcion than at present exists, and the extension was also strongly urged by the late Chilian Minister. A concession was, therefore, obtained from the Chilian Government for a cable from Valparaiso to Talcahuano, about 277 knots, with a land line from Talcahuano to the city of Concepcion. This

Digitized by Google

land line is just completed, and a cable of the most approved type was shipped to Talcahuano in February. From the sailing vessel which carries it out it will be transferred to our steamer "Retriever," and laid under the superintendence of our manager, Mr. Bailey. As to the probable earning power of the extension, we are advised from Valparaiso that we shall have a very considerable amount of traffic over the line. Most of the important English and German houses have established branches in Concepcion and Talcahuano, and the wheat season will give us plenty of business. The principal Valparaiso firms send more telegrams to the south than to any part of the coast, and with a good reliable service we are assured that their telegrams will be trebled. At the last general meeting you were informed that the negotiations with the Brazilian Submarine, and the Western and Brazilian Telegraph Companies, conducted under the auspices of Sir John Pender, G.C.M.G., had resulted in the formation of a new company, the Pacific and European Telegraph Company (Limited), the share capital of which is held by the two Brazilian Companies and this Company. The duplicate line to be run by the new Company from Buenos Ayres to Valparaiso and Santiago, is approaching completion, and will be taken into our offices at Valparaiso and Santiago and worked by our staff, a proportion of the station expenses being borne by the new Company. Now I have given you the present position of the Company; but let me go back to the past, and, although I am not going to prophecy, I wish also to give you my ideas as to the future, and my reasons for forming those ideas. In the case of a new company which has not paid any dividend, the shareholders, after a time, begin to get sick of it; but in the case of a company that has paid a dividend, and a good dividend, such as the West Coast of America Company has done, it is a great pity to see it, from no act whatever of the direction, fall into the list of non-dividend paying concerns. You will remember that your late partner—the Central and South American Company—worked with you for a considerable time under a certain agreement, and the expenses of your ship were paid for by both companies, which was a considerable saving. One fine day, without any rhyme or reason, you got notice to terminate that agreement. Your Board at the time offered to do everything in their power to prevent another cable, which was not required, from being laid along-side yours. I believe they went so far as to promise to hand over the entire working of the West Coast of America Company to the Central Company on condition that the debenture interest, which is very heavy, namely, 8 per cent. on £150,000. and a certain dividend to the shareholders should be guaranteed out of the first receipts. However, the only answer received to that offer was that the Central Company had made other arrangements. Your Directors then looked about to see what could be done. Directly they found that your lines were likely to be cut off from their former communications they applied to Sir John Pender, who is connected with the largest telegraph systems in the world, and he took the matter up, and tried to negotiate with the Central Company, but without avail. Then Sir John and several other gentlemen endeavoured to buy the Trans-Andine line, but they found that the other company were bidding for it also. Our combination bid a little more than the cost of this Trans-Andine line, taking it that, as a going concern, it was perhaps worth a little more; but their efforts were of no avail whatever, and so the matter was left alone, and the Trans Andine was finally purchased by the Central Company. However, immediately after the sale had taken place to our competitors, a company was brought out, with Sir John Pender and several other gentlemen on the Board, and concessions were procured to get a new line laid from Buenos Ayres to Valparaiso. That line has been in course of construction for some months, so that in about two, or, at any rate, three months it will be opened for traffic, and you will therefore have again the means of communication from the West Coast of America to Europe, and be in a much better position. In the case of this new line that is being made, the debenture interest is guaranteed by the West Coast and the two Brazilian Companies, and therefore you are not only bound to them by a working agreement, but you are bound also financially, which perhaps makes a stronger bond between you than any other. It does not stop there. I believe it is a known fact in railway organisation and railway working that expresses running between, say, two of the largest cities would not be remunerative to the companies concerned, but it is the feeders into these cities, and the feeders to the principal stations, that fill up the trains. This is even more the case in telegraphy, because although long lines between two points, would not pay by themselves, the different feeders into the towns or countries at which the main cable touches help very materially to make them pay. Your present position is this: you are now closely connected with the Brazilian Companies, which, in their turn, work with the Eastern Telegraph Company and the Eastern Extension Telegraph Company, and through the working rights which exist between all these Companies you have become part of the largest system in the world. I am not going to prophesy, but I have simply stated what I know about your position, and I leave you to form your own opinion about it. My confident belief is that the West Coast of America Company is on the eve of being placed in a better position than it has ever been in before. I believe that what I have said, and the description I have given, will go to the shareholders who are unable to be present, and I hope it will have the effect of preventing them from throwing their shares on the market and abandoning the Company. I now beg to move:—

"*That the report and the accounts to December 31, 1892, now presented, be received and adopted.*"

Mr. HENRY ROBERTS seconded the motion, which was carried *nem. con.*

On the motion of Mr. ROBERTS, seconded by Mr. PACE, the retiring Directors, Mr. J. Denison Pender and Mr. Frederick Walters, were unanimously re-elected to their seats at the Board.

The auditor, Mr. John Francis Clarke, was also re-appointed, and a vote of thanks having been accorded to the Chairman and Directors, and briefly acknowledged by the former, the proceedings terminated.

Great Northern Telegraph Company.

The following is an abridged report of the proceedings at the general meeting held at Copenhagen on the 29th ult., F. Zahle, Esq., presiding:—

The Chairman of the Company, C. F. TIETGEN, Esq., in rendering an account of the working of the Company during the year 1892, referred to

The Company's Cables, which, he said, had remained in very much the same condition as the previous year. In Europe there had been eleven interruptions, one of which, on the cable connecting England with Norway and Sweden, was remarkable as being the first interruption of that cable since its submersion twelve years ago. The cable steamer "H. C. Orsted" had been on active service for 104 days. In the Far East there had been thirteen interruptions of the cables, and the Company had, when effecting the necessary repairs, taken advantage of the opportunity to renew and strengthen the cables in the most exposed places. This applied especially to the cables between Shanghai and Nagasaki. The value of the spare cable thus employed had been debited to reserve fund account. The cable steamer "Store Nordiske" had been engaged on cable work for 258 days, 90 of which had been for account of others, including the Government of Hong Kong, for whom a cable had been laid between Hong Kong and the recently-erected lighthouse on Gap Rock Island.

Working Account.—He considered this the right place to mention an alteration that had been made with regard to the way of dealing with the profits and expenses of the cable steamers in the accounts. Hitherto the profits accruing from the hire of the cable steamers had been deducted from the expenses, which might give rise to misapprehension, as in consequence of this deduction the accounts did not show the amount of the actual expenses. In last year's account, however, this had been put right, and no deduction had been made under the item "ordinary supervision and maintenance of the sea and land lines and repairing steamers 'H. C. Orsted' and 'Store Nordiske,'" whilst the money earned by the cable steamers had been taken into account under "sundries." This would explain the apparent increase of those two items.

The Situation in China.—For some years he had had very little to communicate to the shareholders with regard to the situation in China, and the relations between the Company and the Chinese Telegraph Administration. The so-called Chefoo agreement had never come into force. As explained on former occasions, the chief object of this agreement had been to reconcile the interests of the new telegraph route, which the Chinese were anxious to open up by way of the Siberian frontier, and the interest of the two old routes, which connect Europe with China by means of submarine cables. As long as the new line had not been put into operation by the junction of the Chinese and Russian telegraph systems, the Company had had no difficulty in dispensing with the agreement. Last autumn, however, a convention with regard to this junction had been concluded between Russia and China, in which the principles regulating the future relations between the different routes had been laid down in a very impartial spirit. In accordance with the fundamental rules of the International Telegraph Convention, it had been stipulated that the three routes should transmit telegrams at equal rates, and there would thus be no competition of rates, but only a competition as to the efficiency of the respective lines. A uniform rate of 8.50fr. per word had been fixed by all three routes between any place in Europe and any place in China, which represented both a simplification of the rates and a reduction for all towns in the interior of China. The new route had been open for traffic since March 1st last. The competition thus inaugurated would probably have the effect of decreasing the revenue of the old routes, and especially that part of it which was derived from the limitrophe correspondence between Russia and China. Still, provided the stipulations of the Russo-Chinese Convention were loyally carried out by the Chinese, the Company felt so confident of the superiority of their own service that they had no serious misgivings on this head.

Financial Results.—After all, however, matters called for great circumspection and caution, the more so as the traffic receipts were over £21,000 lower than the previous year. This was partly due to the fact that the reduced rates fixed at the International Telegraph Conference at Paris, had been in force the whole of 1892, whilst in 1891 they were in operation during the last six months of the year only. It was also partly due to the continually-decreasing rate of exchange of the silver dollar, which affected the Company's remittances from the Far East in a very marked manner.

Distribution of Profits.—These considerations rendered it advisable to place the same amount as last year to the credit of the reserve fund, whilst the Board of Directors had been enabled to recommend that the total dividend be fixed at the same amount as for the two previous years, viz., 17s. 2d. per £10 share, or about 8·60 per cent.

The following resolutions were submitted to the general meeting, and carried unanimously:—

"*That the report and balance-sheet, together with the propositions as to the distribution of the balance, be adopted and discharge given to the Board of Directors.*"

"*That the retiring Director, M. Melchior, Esq., be re-elected as member of the Board of Directors.*"

"*That A. Berner, Esq., and S. Bille, Esq., be re-elected as auditors of the Company.*"

Submarine Cables Trust.

The twenty-second ordinary annual meeting of the certificate holders in the Submarine Cables Trust was held yesterday (Thursday), at the offices of the Trust, Winchester House, E.C., Sir John Pender, G.C.M.G., M.P., presiding.

The SECRETARY (Mr. A. Brodrick) read the notice covening the meeting and the minutes of the last meeting, which were signed as correct.

Digitized by Google

The report of the Trustees having been taken as read,

The CHAIRMAN said: The revenue for the past year amounted to £23,102, as against in 1892 £22,799, showing an increase of £303. The income derived from our investments in the Eastern and Eastern Extension Telegraph Companies is the same as last year, but there is an increase of £307 in that derived from our investment in the Anglo-American Stock. The expenses of the year amounted to £1.627, as compared with in 1892 £1,186, or an increase of £441. This is due to the appointment of two additional Trustees which was made at the ordinary meeting last year, and the legal expenses in connection with the alteration of the Trust deed and the transfer of the investments of the Trust in the names of the additional Trustees. Our revenue during the year has enabled us to pay two coupons of £3 each, and to pay off an additional 7s. 6d. of the overdue coupon. There remains still a balance of £1. 10s. in arrear, but should the dividend on our investments be maintained this arrear will be gradually paid off. I may mention that we received one letter in regard to the appointment of two extra trustees; but this is not a question of Directors; it is a question of trustees, and we are bound by our Articles of Association to appoint them. Our solicitor informs us that we must act strictly in accordance with these, and that accounts for the circumstance. The prosperity of the Trust depends entirely on the successful working of the different submarine cable companies in which we hold investment. Some of these at present are looking very healthy, and with the increasing prosperity of telegraph companies generally, we hope that this Trust's dividend will be maintained. He concluded by moving the adoption of the report.

The Marquis of TWEEDDALE seconded the motion, which was carried unanimously.

The auditors—Messrs. John G. Griffiths and John Gane—were re-appointed, on the motion of Mr. SHUTER, seconded by Mr. CUNLIFFE OWEN; and a vote of thanks having been passed to the Chairman and Trustees, which the former briefly acknowledged, the proceedings ended.

African Trans-Continental Telegraph Company (Limited).

The first ordinary general meeting of this Company was held on Thursday last week at 19, St. Swithin's-lane. Mr. Albert Grey presided in the absence of the Duke of Abercorn.

The SECRETARY (Mr. C. H. Weatherley) read the notice convening the meeting.

The CHAIRMAN said: This meeting is the first ordinary general meeting of the Company, and is purely formal. As no Articles of Association have yet been adopted it is necessary for the Directors to place their resignation in the hands of the shareholders. These gentlemen offer themselves for re-election. He then stated that a capital of £140.000 has been secured, this being the sum estimated to be necessary for carrying their telegraph line as far as Uganda. You will be glad to hear that the material for the first 400 miles has been ordered, and will in a very short time be shipped, one half going to Chinde Mouth, and the other half to Beira, for transport to Salisbury *viâ* the Beira Railway, arrangements having meanwhile been made in South Africa to construct the line from Salisbury as far as Zomba, the British Residency in Nyassaland. Thus you will observe that the first step has been taken towards the construction of the telegraph which is eventually to connect Cape Town with Cairo. I think it right to mention that by far the greater part of the capital has been provided by Mr. Rhodes, who, with unexampled generosity, has undertaken to find such portion of the £140,000 as may not be forthcoming from other quarters by the end of June. I trust this example of patriotism is one which wealthy capitalists in England will take to heart. I confess, speaking as an individual Englishman, and not as a Director of this Company, I am jealous for the sake of England that the honour of constructing this Imperial telegraph, required in the interests of the Empire and for the service of humanity, should belong so exclusively to an Englishman, however distinguished he may be, whose home is in South Africa. I am convinced that there are in this country large numbers of people, both great and small, who would dearly covet the privilege of being allowed to co-operate with Mr. Rhodes in the promotion of this Imperial undertaking. I believe the only reason why many have not already subscribed is that they do know how to avail themselves of the opportunity which is still before them. It was the ambition of Mr. Rhodes to get the money required for this telegraph subscribed in small sums, so that he might have the satisfaction of knowing that the people of England were at his back. I hope that this legitimate ambition may be gratified. I have now to propose—

"*That the retiring Directors, his Grace the Duke of Abercorn, K.G., and Messrs. C. J. Rhodes, Albert Grey, Rochfort Maguire, S. Neuman, and J. Werner, be and the same are hereby re-elected as Directors of this Company.*"

This resolution was proposed by Mr. PADDON, seconded by Mr. WATKINS, and unanimously adopted.

Elmore Patent Copper Depositing Company (Limited).

Mr. J. J. Atkinson presided on Friday at the adjourned meeting of the Company, and explained that the meeting had been adjourned for the purpose of electing a committee to confer with the Board in order to get the capital subscribed to carry on the Company, and to receive the resignation of the old Directors. That resignation was tendered, and the gentlemen who proposed to act, under certain conditions, as the new Board, were Messrs. Todhunter, Owen, Jones, and J. W. Daley, who formed part of the committee appointed at the last meeting.

Mr. TODHUNTER said the committee had conferred with the Directors, who came to the conclusion that it would be useless to ask the shareholders to go on and find further money if the original Directors remained in office. He spoke of the difficulty in getting gentlemen to act on the new Board, and added that it had therefore become necessary for them, on the part of their committee, to take up that position themselves. They would only, however, take office on the condition that the capital which was required was subscribed up to the hilt. If that capital were forthcoming he was inclined to believe that the Company would eventually prove a success, for he was firmly persuaded of the value of the process which they possessed.

General BEADEL severely censured the previous management of the Company, as did other shareholders. The following resolution was subsequently carried—

"*That this meeting be adjourned for fourteen days, and that, in the meantime, a circular be sent out showing the names of the gentlemen who are willing to take office as Directors provided 8,800 preference shares be in the meantime subscribed, and upon the understanding that if the shares are not fully subscribed any money paid on the same shall be repaid in full.*"

Western and Brazilian Telegraph Company (Limited).

The following is the report of the Directors to be presented at the twenty-fifth ordinary general meeting of the Company, to be held at Winchester House, Old Broad-street, E.C., on Thursday next, the 11th inst., at 12 noon:—

The total earnings for the half-year ended December 31, 1892, amount to £86,954. 11s 2d. as against £92.345. 4s. 7d., showing a decrease of £5.390. 13s. 5d. compared with the half-year to December 31, 1891. The working expenses amount to £37.165. 11s. 5d. as against £38,404. 5s. 1d., a decrease of £1.238. 13s. 8d. Including the amount brought forward from June 30, 1892 (£1,662. 5s. 3d.), and the dividend received upon the shares held in the "Platino" Company, the balance to the credit of the revenue account is £58,838. 5s., from which has been deducted £12,426 for debenture interest, and £6,674 for the debenture redemption fund, leaving £39,738. 5s., of which £15.000 has been placed to the reserve fund. The Directors now recommend the payment of a dividend of 4s. 6d. per share, free of income tax, for the half-year on the ordinary shares, making, with the dividend paid in November last, £2. 10s per cent. for the year, leaving a balance of £2,829. 15s. 6d. to be carried forward. In the case of shares which have been divided into "preferred" and "deferred," the 4s. 6d. per share now recommended will be payable to the "preferred" shareholders, making up the full dividend on the preferred shares for the year 1892.

The fourth annual drawing of the "A" and "B" debentures took place at the Company's offices on January 16th last in the presence of Mr. W. W. Venn, jun., notary, when debentures amounting to £13,300 were drawn, and have since been paid off at par.

The Company's new repairing steamer frequently referred to has left for her station on the coast of South America. The duplication of the cables over the greater part of the system renders it feasible, in the opinion of the Directors, satisfactorily to maintain the cables with only one repairing steamer, and consequently tentative measures are being taken with this object.

The new cable *viâ* French Senegambia was opened for traffic on October 5th last, and was in active competition with the old system from that date until December 27th, when it became interrupted. It was repaired on February 9th of this year. A further reduction in the tariff for messages exchanged with Brazil, Uruguay and the River Plate, came into operation on April 1st last.

The land line connecting Buenos Ayres with Valparaiso, regarding which the shareholders have already been informed, is approaching completion, and the Directors are given to understand will be in operation about the end of June next.

The dividend warrants will be posted on May 12, 1893.

The retiring Directors are Mr. W. S. Andrews and Mr. J. Coppen, who offer themselves for re-election. The auditors, Messrs. Turquand, Youngs, Weise, Bishop, and Clarke, and Messrs. Deloitte, Dever, Griffiths, and Co., retire and are eligible for re-election.

Yorkshire House-to-House Electricity Company (Limited).

The following is the report of the Directors, to be presented to the Ordinary General Meeting, to be held at the Central Electric Lighting Station, Whitehall-road, Leeds, on Friday next, May 12th, at 3 p.m.:—

The Directors submit a statement of the income and expenditure for the past year, and the balance-sheet showing the assets and liabilities of the Company made up to December 31st last. It is intended in future to make up the accounts to December 31st in each year. It will be seen that the balance at credit of the net revenue account is £11. 11s. 3d., which amount it is proposed to carry forward.

The plant for the first installation of the Company's works is now practically completed, and, it is expected, will be in operation at or before the date of the coming general meeting, when the Directors hope that a large number of the shareholders will avail themselves of the opportunity of inspecting it.

In response to applications from intending consumers, some extensions of mains have been carried out since the last general meeting, and the total length of culverts now laid is about 12.000 yards. In order to meet the urgent requirements of important customers, electricity has been supplied since December 14th last from temporary plant erected on part of the Company's spare ground. This supply has been maintained without interruption or irregularity, although the conditions under which it was

Digitized by Google

generated were not so favourable as will be the case in running the permanent plant. The only drawback has been the impossibility of giving the supply to more than a very small proportion of the applicants. The applications for current already received are equivalent to about 10,000 lights. The demand is still growing at a very satisfactory rate, and will, it is anticipated, at an early date render it desirable to increase the capacity of the Company's plant.

The retiring Directors, Mr. Robert Hudson and Mr. Samuel Ingham, being eligible, offer themselves for re-election. Mr. John Gordon, jun., offers himself for re-election as Auditor.

NEW COMPANIES, STATUTORY RETURNS, &c.

[In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in "The Electrician" Electrical Trades' Directory and Handbook, 1893, pages 320-348, &c., &c.]

ALADDIN PRIMARY ELECTRIC BATTERY COMPANY (LIMITED).—This Company was registered on April 28th with a capital of £6,000 in £10 shares, to acquire the patent rights of Mr. Theophilus Coad in a primary battery and electric miners' safety lamp, also to acquire the secret for the manufacture, and the right to manufacture the fluid used in the battery, and to carry on the business of an electric-light, heat, and power supply company, and as electricians, mechanical, and electrical engineers, &c. The subscribers, with one share each, are:—T. Coad, Tottenham, electrician; A. Saunders, 21, Great St. Helens, E.C.; H. Bonner, 40, The Avenue, Gipsy Hill, S.E.; Percy M. Mountain, Hawtree, West Dulwich; Joseph Walton, 132, Christchurch-road, Tulse Hill; William Hope, High-street, Wimbledon; Henry S. Mountain, Selsdon-road, West Norwood. The first Directors are T. Coad, H. Bonner, P. M. Mountain, and A. Saunders.

ELECTRICITATS-GESELLSCHAFT GELNHAUSEN.—Under this title a limited liability company has just been formed, with a capital of 650,000 marks, to take over and carry on the business of the Gelnhausen branch of the Electriciteits-Maatschappy of Rotterdam. The new Company acquire the De Khotinsky patents for Germany, and will manufacture incandescent lamps, accumulators, and all kinds of electrical apparatus.

GEORGE HENDRY AND CO. (LIMITED).—Capital, £3,500 in £10 shares, as copper smiths, metal founders, and art metal workers, at Oat-lane, Church-row, Limehouse, London, E.

PERKINS AND BELLAMY (LIMITED).—This Company was registered on May 1st with a capital of £70,000, in 2,000 £6 per Cent. Cumulative Preference and 5,000 ordinary shares of £10 each, to carry on the business of agricultural and electrical engineers, contractors, &c., at Ross and Hereford.

RAINBOW ENGINEERING COMPANY (LIMITED).—This Company was registered on May 1st, with a capital of £20,000 in £5 shares, to carry on the business at Albany-buildings, Victoria-street, Westminster, S.W., of electricians, suppliers of electricity for the purposes of light, heat, motive power, or otherwise, and manufacturers of and dealers in all kinds of electrical and scientific apparatus.

ZOHRAB AND BIGGS ENGLISH PATENTS (LIMITED).—This Company was registered on May 1st, capital £32,007, in 3,200 deferred shares of £10 each and seven preferred shares of £1 each, to acquire certain letters patent granted to Messrs. Zohrab and Biggs for improvements in railway signalling.

CHELSEA ELECTRICITY SUPPLY COMPANY (LIMITED).—An agreement, made April 15th, between the Cadogan Electric Light Company (Limited), in liquidation, Arthur Greenwood (liquidator), William B. Peat (Receiver and manager), and the Chelsea Company states that, whereas the Cadogan Company is in liquidation, it was agreed that the Chelsea Company should purchase all the leasehold premises, stock-in-trade, plant, &c., the benefit of all contracts, and the sum of £250 lodged with the Metropolitan Board of Works, from the Cadogan Company for £10,250. The said sum is to satisfied as to £2,000 by the issue to the vendors or their nominees of second mortgage debentures of the value of £2,000, £5,000 by the allotment and issue to the vendors of 1,000 fully-paid ordinary shares of £5 each, and £3,250 by four acceptances of equal amounts payable at three, six, nine, and twelve months after the date of the completion of the purchase.

CITY OF BATH ELECTRIC LIGHTING AND ENGINEERING COMPANY (LIMITED).—The annual return of this Company, made up to March 25th, has been filed. Out of a nominal capital of £60,000, 5,500 ordinary shares, of £10 each, and 50 founders' shares of £100 each, 3,334 of the ordinary, and all the founders' shares have been taken up. 2,250 ordinary and the founders' shares have been issued as fully paid, and the full amount has been called on the remainder, resulting in the payment of £10,770.

DICK, KERR AND CO. (LIMITED).—The annual return of this Company, made up to April 12th, has been filed, showing that the whole nominal capital of £160,000, divided into 16,000 ordinary and 16,000 preference shares of £5 each has been taken up.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The annual return of this Company to April 7th has been filed. Out of the nominal capital of £95,000, divided into 13,000 ordinary and 6,000 preference shares of £5 each, 12,931 ordinary, and 6,000 preference shares have been taken up. Upon the preference shares the full amounts have been called, and upon the ordinary £4 per share, resulting in the payment of £81,724.

ELECTRICAL ENGINEERING COMPANY OF IRELAND (LIMITED).—A resolution was passed on March 24th, and confirmed on April 17th, that the Company be wound up.

ELMORE'S FRENCH PATENT COPPER DEPOSITING COMPANY (LIMITED).—A petition for the compulsory winding up of this Company was presented on the 25th ult. by the Securities Insurance Corporation (Limited), and is down for hearing at the Royal Courts of Justice on May 17th.

FROUDE-HURRELL TORPEDO COMPANY (LIMITED).—Proofs of debts against this Company (in liquidation) must be sent in to Mr. C. J. Stewart, the liquidator, at 33, Carey-street, W.C., by the 13th inst.

JOHANNESBURG LIGHTING COMPANY (LIMITED).—The annual return of this Company to April 20th is filed, showing the nominal capital to be £150,000, in 50,000 preference and 100,000 ordinary shares of £1 each. 50,000 preference and 77,132 ordinary have been taken up, of which the preference and 77,125 ordinary were issued as fully paid in exchange for fully paid shares in the South African Company of the same name.

KESWICK ELECTRIC LIGHT COMPANY (LIMITED).—The annual return of this Company, made up to March 14th, has been filed. 3,420 £1 shares out of a total of 5,000 have been taken up, the full amount called, and all calls paid.

LEEDS AND LONDON ELECTRICAL ENGINEERING COMPANY (LIMITED).—The annual return of this Company, made up to January 2nd, has been filed. The nominal capital is £100,000, divided into 250 founders', 9,750 preference, and 10,000 ordinary shares of £5 each. All the founders', 734 preference, and 8 ordinary shares have been taken up. Upon the founders', 634 preference and 8 ordinary shares, the full amounts have been called, and upon the remaining 100 preference shares a call of £1 per share has been made. The calls paid amount to £4,530.

TAUNTON ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return of this Company, made up to March 14th, has been filed. Out of a capital of £20,000, in £5 shares, 2,569 have been taken up, of which 787 have been issued as fully paid. Upon the remaining 1,782 the full amounts have been called, and all calls (£8,910) paid.

TELEPHONE COMPANY OF EGYPT (LIMITED).—This Company's annual return, made up to April 25th, is filed. The nominal capital is £100,000 in 16,000 preferred and 4,000 deferred shares of £5 each. 12,071 preferred and 4,000 deferred shares have been taken, and with the exception of 71 preferred, issued as fully paid. Upon the last-named shares the full amounts have been called, and all calls paid.

WOKING ELECTRIC SUPPLY COMPANY (LIMITED).—The annual return of this Company, made up to December 31st last, has been filed. The nominal capital is £20,000, in £5 shares, and 2,965 shares have been taken up. Of these 2,873 were issued as paid. Upon 20 shares 5s. per share has been called, upon 20 more 10s. per share, and upon the remaining 57 shares 25s. per share, resulting in the payment of £85.

CITY NOTES, &c.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended April 30th were £792, as against £794 for the corresponding period of last year, being a decrease of £2. The total receipts for the half-year amount to £15,360, against £14,096 in the corresponding period of 1892, being an increase of £1,264.

CONSOLIDATED TELEPHONE CONSTRUCTION AND MAINTENANCE COMPANY (LIMITED).—A petition for confirming a resolution reducing the capital of the above Company from £307,545 to £234,938 has been presented to Her Majesty's High Court of Justice.

CONTINENTAL METROPOLITAN TRAMWAYS COMPANY (LIMITED).—At the meeting, recently held, of this Company Mr. B. H. Van Tromp (the Chairman) notified the shareholders that in Paris the Directors were trying to find some method of mechanical traction which they could economically adopt. A suggestion was under consideration for the use of a peculiarly constructed engine for their long lines, but at present he was unable to notify any progress in the matter.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the month of April are £3,900, as compared with £3,738 in the corresponding month of last year.

DIRECT SPANISH TELEGRAPH COMPANY.—The gross receipts for the month of April were £1,742.

EASTERN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of April amounted to £56,469, and to £53,683 in the corresponding period of 1892, an increase of £2,786.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of the Eastern Extension, Australasia and China Telegraph Company (Limited) for the month of April, 1893, amounted to £41,713 and to £38,824 in the corresponding period, of 1892; increase, £2,889.

ELMORE'S GERMAN AND AUSTRO-HUNGARIAN METAL COMPANY (LIMITED).—A report of the proceedings at the second ordinary general meeting of this Company, held on Wednesday, will appear in our next issue.

Digitized by Google

GREAT NORTHERN TELEGRAPH COMPANY.—7s. 2d. per £10 share, representing the final dividend for 1892, are now payable at the Company's bankers, Messrs. C. I. Hambro and Son, No. 70, Old Broad-street, London, E.C., against coupon No. 27.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED.—The traffic receipts for the week ended April 28, 1893, after deducting 17 per cent. of the gross receipts, payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,074.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 782.—Vol. XXXI. FRIDAY, MAY 12, 1893. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

Electrical exhibits at the Royal Society Conversazione were as numerous as usual, but no novelties of special interest were shown. Mr. Campbell Swinton showed his high-frequency experiments, and by running a five-candle 100-volt lamp through his body will—though he himself has done all that he can to correct it—encourage the idea that high-frequency currents produce small physiological effect. An interesting demonstration of the simple way in which these currents obey Ohm's law, was shown when Mr. Swinton took the current, probably a small fraction of a milliampere since he could hardly feel it, from hand to hand, and lighted the lamp. On bringing his hands together, the lamp became brighter, the resistance offered by his body being thus short-circuited. On separating his hands a little, sparks, which by their length showed the presence of thousands of volts, passed between them. Similarly, two or more persons may grasp hands, the lamp will be dimmed, and on short-circuiting any one of the experimenters, sparks will pass. The current in these experiments seem still to defy measurement. A comparison between the heating of two fine wires of different diameters might eliminate the skin effect, but the estimation of anything but the watts is surrounded with considerable difficulties. Among other matters of electrical interest were Major Holden's instruments, Mr. Callendar's thermometers, Rev. F. J. Smith's inductoscript figures, Sir David Salomons' photometer, which is fully described in another column, and last but not least, demonstrations by Lord Armstong, of the transference of a cotton thread, and of water currents under electrification, and of remarkable dust figures produced by spark discharges in air.

Mr. Swinton used about 20 amperes for his induction coil, taking the current from the mains supplying Burlington House. In another room Prof. Ewing was showing his curve tracer. The beautiful sweeps of those curves which have become associated with the name of Ewing, as the Japanese butterfly with the name of Whistler, were thrown on a screen, but every now and then threw themselves into wild contortions, wreaths of wriggles, and intricate sinuosities. These were due to the interruptions of the primary current of Mr. Swinton's coil, the mains being hardly large enough for both experiments at the same time. Scientifically, the curves were spoiled, but for conversazione purposes they were greatly improved; for at conversazioni something is wanted which shall be in the first place agreeable to look at, in the second place not self-evident, but in the third place, explicable in a few words. Organisers of such exhibitions, have a wide field open to them in the combination of totally different experiments.

Sir David Salomons and Mr. Pyke exhibited some pretty vacuum tubes and an alternator of an output of two million micro-amperes at a frequency of 262,800,000,000 per annum, and running with a relative speed of about 36,000,000 revolutions per week. It is not usual to describe alternators in this way, but as the exhibitors seem to have departed from the usual practice simply for the sake of big figures, we adopt their suggestion. A confused use of "alternation rapidity" instead of "frequency" is made for the sake of doubling the figure, and by taking alternations per minute instead of complete periods per second, as is the custom of all English engineers, the figure is increased 120-fold. As far as we can make it out the frequency is really only about 9,000. The Ewing-Parsons machine gives 14,000 complete periods per second, and Tesla used 13,000. Whatever it may be, no new phenomena seem to have resulted.

We are extremely glad to see that the Chairman of Ways and Means has given notice that he will to-day move the following:—

"Electric Powers (Protection clauses).—That a Joint Committee of Lords and Commons be appointed to consider and report whether the grant of statutory powers to use electricity ought to be qualified by any prohibition or restriction as to earth-return circuits, or by any provisions as to leakage, induction, or similar matters; and, if so, in what cases and under what conditions. And if the Joint Committee are of opinion that any such prohibition, restriction, or provision should be enforced, to settle the necessary clauses. That a message be sent to the Lords to communicate this resolution, and desire their concurrence."

We trust that no effort will be spared to present the case for electric traction in the clearest possible light. It should be borne in upon the Joint Committee that it is solely and wholly a question of Cheap Traction *v.* Bad Telephony. Those who are interested in electric traction will do well to remember that whatever decision the Joint Committee arrives at will have more or less of a finality character; and if they do not wish the decision to go against them by default, they must be up and doing now. It is expected that the Joint Committee will sit immediately after Whitsun.

The electrical industry in this country should take note that in Philadelphia the comfortable doctrine is being preached

Digitized by Google

that "the People have a moral right to rapid transit." It would not be a bad stroke of business for the Electric Traction Association, now in process of incubation, to import the doctrine and the preacher thereof into this country. Were the public thoroughly imbued with this notion by a persuasive peripatetic orator, it would give a much-needed fillip to electric tramways, and act as a counterblast to the telephone protection clauses in existence or in contemplation. When once it is properly understood that there is no "greater injustice" than "to compel weary men and women, worn with the strain of a long day's work," to walk home, it will be obvious that there can be no greater injustice than to compel weary men and women to do a long day's work in stuffy rooms filled with gas fumes. This is, indeed, "a consummation devoutly to be wished," and it conjures up visions of the Beckton gasometers converted into cool storage tanks, and the palatial headquarters in Horseferry-road transformed into a home for decayed gasmen.

The movement in favour of the municipalisation of the telephones seems a veritable *deus ex machina*. No one is particularly satisfied, either from the engineering or the public point of view, with the present state of telephony in England. On the other hand, no one loves Government control if it can be avoided. A few weeks back we chronicled the fact that the Glasgow Corporation contemplated applying for a telephone licence, and now, as will be seen in our Notes column this week, Manchester appears to be tending to a like policy. The question arose over an application by the National Telephone Company for permission to run some of its wires under the streets, and Dr. John Hopkinson has been instructed to prepare a report upon the subject of underground telephone wires in general. From what passed at the meeting of the Town Council it would seem as if they meant to have all and every telephone wire placed underground. It is to be doubted whether there is any real need for such a drastic measure, and there can be no doubt that it would be unjust to compel a company to adopt so expensive a system without giving it a more secure tenure than is, perhaps, altogether advisable. Overhead telephone wires, as they are now being run in London neatly over the housetops and across the streets, in the majority of cases at a suitable angle, do not seriously offend the eye and are not a source of danger to the public. Inter-exchange cables, on the other hand, ought to be and are being everywhere put out of sight, or, as in the case of the hideous catenary which until recently threatened the traffic on the south side of Trafalgar Square, should be separated into a hardly visible band of fine wires.

Electrical measurements have of late years been tending to divide into distinct classes. One of these consists of measurements of precision, in which complicated and delicate apparatus can be employed, where time is but of little importance, where the "fifth figure" is a laudable aspiration, and where a set of instruments can sometimes be set up and kept for special work. The other extreme is the use of simple direct-reading instruments, of what may be called the switchboard class, to measure current and volts. The dials are, or should be, as legible as those of steam-gauges; an accuracy of one-half per cent. is claimed, and an accuracy of something better than one per cent. is commonly attained. But there is plenty of room for electrical measurements which fall between these two classes, such, for instance, as have to be made daily in the testing-room of an electrical factory or of a municipal authority. Laboratory instruments as well as laboratory methods are not well suited for such work. One-quarter per cent. must be attained, though an error of a-sixteenth of an inch in a two-foot rule exceeds this, and is more common than is generally imagined.

Calling the intermediate class of instruments testing-room instruments, these must be simple, direct-reading, easily read, always ready for use, and are all the more valuable if they are suitable for a variety of work. At such an instrument Mr. Crompton has been working for several years. The principle is old enough, and that is in itself, perhaps, a very considerable advantage. It is a potentiometer, but a very different affair to the slide-wire arrangement generally seen in laboratories. By successive improvements upon the form devised by Dr. Fleming, and by the use of manganin, a degree of accuracy has been arrived at which raises this apparatus to a high class, while it retains all the simplicity necessary for engineering use. A full description of a Crompton potentiometer suitable for verifying voltmeters to one-tenth of a volt, for testing meters to one part in 1,000, and for measuring from one milliampere to 5,000 amperes or more, will be found in another column. It will be seen that Mr. Crompton relies entirely on the Clark cell, and the severe tests to which this invaluable standard has been put during the last two years or so show that it is fully worthy of the confidence which he places in it. It is not possible in this article to give a complete description of the many ingenious details of construction of his instrument. The stretching devices, the rheostat, and the adjustment of the fourteen coils are all of great interest, and are the outcome of much careful work by Mr. Crompton himself in his private laboratory, resulting in a most useful and accurate instrument.

We have been requested to contradict the rumour, which has, we learn, obtained considerable credence, that the failure of the electric light in the precincts of the House of Commons on Monday evening last was caused by an impatient Cabinet Minister cutting short the debate by short-circuiting the main fuse with a bradawl. The following letter from the Secretary of the Westminster Electric Supply Corporation gives the true version of the incident. We may add that although 500 amperes were thus suddenly thrown off the plant without warning, nothing went wrong at the station :—

Sir,—With reference to the statement in many of this morning's papers to the effect that the extinction of the electric light at the House of Commons last evening is understood to be due to some failure in the supply furnished by an Electric Lighting Company, as secretary of the Lighting Company I beg to inform you that such extinction was not due to any failure or fault in this Corporation's supply, but was owing to the melting of a safety fuse in the House itself, over which the Corporation has no control. The Westminster Corporation has never failed in its supply since its first commencement.

Digitized by Google

As a matter of fact, however, in these days of the "all-by-electricity" mania, a switch for turning the lights out whenever further debate became inconvenient, placed by the Premier's side, would be, as penny-a-liners say of wedding presents, both useful and appropriate.

At a well-attended dinner held at the Whitehall Club on Friday last, the proceedings being otherwise of a private character, the following telegram was sent:—

CLOWRY, Chicago, for ELISHA GRAY.

The Electrical Engineers of England, dining together at their Club to-night, desire to convey to their professional brethren in Chicago sincere congratulations upon the opening of their grand Exhibition. We hope to appear in person in August next to support the success of your magnificent undertaking. PREECE, Whitehall Club. May 5.

Whatever views may be held as to the utility of English firms exhibiting at Chicago, or whatever other opinions may be held about the Exhibition, this expression of friendly congratulation may be taken as representing English appreciation of the energy which has carried the enterprise through, notwithstanding many adverse circumstances and a general lack of enthusiasm outside the United States.

Wakefield.—The Town Council have decided to apply for an Electric Lighting Order.

Lord Kelvin.—It is announced that the Italian Minister of Public Instruction has nominated Lord Kelvin to be a member of the Academy of Naples.

Coventry.—Mr. Graff Baker hopes to have his electric cars running by August, and intends to start the electrical equipment of the line immediately.

Obituary.—We have to record the death, in his eightieth year, of Dr. Mathäus Hipp, which took place at Zurich on the 3rd inst. Dr. Hipp was one of the pioneers of electric telegraphy on the Continent, and invented a great number of electrical instruments and apparatus.

Owens College, Manchester.—At least two Bishop Berkeley Fellowships, of the value of £100 per annum, are offered for award in June next. Evidence must be presented of ability to prosecute some special study or research. A limited number of appointments to Honorary Research Fellowships will be made on the same date.

Halifax.—At the last meeting of the Town Council, the Gasworks Committee recommended that application should be made to the Local Government Board for sanction to a loan of £30,000 for electric light works, and that the electrical engineer should be instructed to prepare all the necessary plans, estimates, and specifications for the scheme. The minutes of the Committee were approved.

Electric Traction for Canal Work.—In a recent message to the New York Legislature, Governor Flower called attention to the possibilities of electric traction for the State Canals, referring especially to the use of the trolley system, and suggested the establishment of power-houses by the State at proper intervals. The Legislature has taken action on this recommendation by appropriating $12,000 to be spent in experiments.

The Central Institution.—The following extract from the annual report of the Dean to the Governors of the Institute may be of interest:—

The staff of the Central Institution still thinks that a more distinctive name would be of advantage to the Institution. Some remarks were made on this point in the report last year. It is hoped that it will not be considered presumptuous if it is suggested that such a title as the "City and Guilds School of Engineering and Technology" would be distinctive and comprehensive.

Testimonial to Prof. Garnett.—On Saturday evening last, in the Physical Lecture Theatre of the Durham College of Science, the artisans and others who attended the winter series of lectures delivered by Prof. Garnett on "The Pioneers of Electricity," presented him, for the use of the College, with two electrical measuring instruments, as a mark of their appreciation of his efforts for their instruction. Alderman W. H. Stephenson presided, and there was a large attendance.

Edinburgh.—It seems that by the constitution of the Edinburgh Town Council, a resolution of the Council does not become final until it has been three times affirmed by the councillors. On the first occasion, the figures in regard to the electric lighting scheme were: For, 20; against, 10. Last time they were: For, 19; against, 16, six members of the Council failing to record their votes. There undoubtedly exists a strong feeling against the proposal that the Corporation should themselves work the undertaking.

Ealing.—At the last meeting of the Local Board the Electric Lighting Committee reported that the plans of the proposed electric light buildings were before the Committee, together with the specifications for boilers, machinery, &c. The Committee came to the unanimous resolution to recommend that tenders for boilers and machinery should be invited forthwith, and that application should be made to the Local Government Board for permission to borrow £25,000. The Report of the Committee was adopted.

Hampstead Vestry.—At the last meeting of this Vestry, the Electric Lighting Committee recommended that the specifications prepared by Mr. Preece for the plant, &c., for the proposed central station should be adopted, and that the necessary advertisement for tenders should be inserted in certain newspapers. The Committee also asked to be authorised to take all necessary steps for carrying out the Hampstead Electric Lighting Provisional Order, and that application should be made to the County Council to advance to the Vestry the sum of £25,000. These recommendations were adopted.

The Telephone at Norwich.—The *Norfolk Standard* is pleased to be able to announce that a new Company has been formed, to be called the Norwich Telephone Company, the object of which is to supply subscribers with a cheaper and more efficient system. The new Company, which is of purely local origin, guarantees complete metallic circuits for £5 annually, for distances not exceeding a quarter-a-mile, £6 for under a half-mile, and £7 for a mile from the exchange. The Company is prepared to go to work as soon as 200 subscribers have been obtained. The new Company has, it is stated, no intention of allowing itself to be absorbed.

Bewdley.—At a recent meeting of the Town Council the Electric Lighting and Water Committee sensibly reported as follows:—Your Committee report that they have made further inquiry on the question of obtaining power from the Severn to supply Bewdley with electric light and for pumping purposes, and have pretty fully investigated one of the schemes proposed, which they think would probably prove successful. It is, however, an untried plan on any large scale; and your Committee are not prepared to recommend the heavy outlay necessary to prove its capability. They have other projects under consideration, and will report upon them in due time.

Electric Supply at Leeds.—The central station at Leeds was formally opened on Wednesday by the Mayor. The station has a capacity of 16,000 lights, of which 10,000 are said to be booked. The furthest lamp is at a distance of about three miles. As the Yorkshire House-to-House Company refused to give any particulars of the plant to our representative before the ceremony, we only received a brief account from him yesterday morning. The plant seems to be of the usual type employed in Mr. Hammond's undertakings, viz., Fowler engines, rope-driving, Lancashire boilers, and Lowrie-Parker alternators. Two 100-kilowatt and one 50-kilowatt machines are provided. Nalder voltmeters and vacuum tube earth testers are used.

Electrical Bills in Parliament.—On Monday the examiners in the House of Commons passed the Electric Lighting Provisional Orders (No. 3) Bill. In the case of the City of London Electric Lighting Company's petition for a Bill it was declared that the standing orders had not been complied with.—In the House of Lords the examiners passed the Brighton and Rotting-

Digitized by Google

dean Seashore Electric Railway. On the same day the House of Lords read the Kensington and Knightsbridge Electric Lighting Company Bill a third time. On Friday last the Select Committee of the House of Lords appointed to inquire into the merits of the Bill promoted by the Dublin Southern District Tramway Company to empower them to acquire the lines of the Blackrock and Kingstown Tramway Company, and to use electrical power upon the entire system, ordered the Bill for a third reading.

Alternating Motors.—Alternating-current motors have, in the opinion of *Industries*, now very nearly been invented. There are many makers who are just bringing them out. For years there have been motors and rumours of motors, but so far there have been none really in the market. We do not know whether even now there are any stocked and sold on an ordinary commercial basis—that is to say, on the same footing as direct-current motors—but the number that are to be put on the market immediately has been increasing rapidly during the last few years. Of course, we are aware that double and triple-current motors have been in use for some time, and that very small and very large alternating motors have been used. The machines that have been so long on the point of bursting into commercial use are 1-H.P. to 10-H.P. single-current motors which start easily and take currents in proportion to their load.

Royal Institution.—At the general monthly meeting on Monday last the honorary secretary reported that the late Earl of Derby had bequeathed £2,000 to the Royal Institution. The special thanks of the members were returned for the following donation to the Fund for the Promotion of Experimental Research at low temperatures:—Mr. Alfred F. Yarrow, £50; Sir David Salomons, £50; Mr. Henry Vaughan, £20. —At the annual meeting of the Royal Institution, held on Monday last week, the annual report of the Committee of Visitors for the year 1892, testifying to the continued prosperity and efficient management of the Institution, was read and adopted. The real and funded property now amounts to above £104,000, entirely derived from the contributions and donations of the members and of others appreciating the value of the work of the Institution. Sixty-three new members were elected in 1892. The books and pamphlets presented in 1892 amounted to about 238 volumes, making, with volumes purchased by the managers, a total of 768 volumes added to the library in the year.

The Decimal System.—Messrs. Willans and Robinson have adopted the metric system in their works. They have taken this course owing to the practical convenience of the metric system and to their conviction that they thus obtain commercial advantages in securing orders in those countries where the metric system is in force, and in order that parts of engines made by them may be interchangeable with those made by their licencees abroad. We are authorised to state that their existing standard sizes of engines, chiefly used for non-condensing purposes, will remain unaltered, in order, among other reasons, to avoid causing inconvenience to present users of their engines, the gauges, templets, &c., only, for the sake of uniformity in the works, being restamped to the nearest hundredth of a millimetre. A new series of engines, however, specially designed for condensing work, which is now in hand, and all new works will be constructed to even measurements on the metric system. Mr. Charles Louis Hett, of the Turbine Foundry, Brigg, contemplates adopting this system of measurement in his works also.

Medical Battery Company v. "Science Siftings."—The Medical Battery Company have, says the *Electrical Review*, withdrawn proceedings against *Science Siftings*, and have paid £1,500 damages, including costs, on the counterclaim. "The ground of action will be better understood," says our contemporary, "if we refer to matters preceding our own lawsuits. It will be remembered that the solicitors of the Medical Battery Company issued some time ago a circular to the newsagents, which stated that if they sold copies of the *Electrical Review* and *Science Siftings* containing libels on their clients they would be held responsible. Practically, the effect of the circular was to prevent many newsagents selling the papers in question. The matter was felt to be serious by us, and we at once commenced proceedings against the Medical Battery Company. The Medical Battery Company replied to this by serving us with a writ for libel, *Science Siftings* being served in a similar manner. A counterclaim was inserted in the pleadings of *Science Siftings*, damages being claimed on similar grounds to ours. The result of our action against the Medical Battery Company must be still fresh in the minds of our readers, and they will be pleased to learn that *Science Siftings* has practically proved its case without going into Court."

The Telephone Question at Manchester.—At a recent meeting of the Town Council the minutes of the Paving, Sewering and Highways Committee stated that a letter on behalf of the National Telephone Company having been considered, the Town Clerk, City Surveyor and Dr. John Hopkinson had been instructed to prepare a joint report upon the subject of underground telephone wires. Mr. Southern said this was a subject of great importance, and required to be approached in a broader way than would be possible by leaving it to a single committee. It should not be considered merely on the initiative of a private company. There were various modes in which the telephonic service might be dealt with. It might be desirable to ask the Postmaster-General to establish a local exchange, or it might be advisable to adopt the same mode as was adopted with regard to the tramways; or, seeing there were two companies in the town, it might be wise to secure competition between them. As a means of having the matter fully considered, he should move as an amendment that the minutes be confirmed except the one relating to the underground telephone wires, and that a special committee be appointed to inquire into the system and report upon the expediency of placing telephone wires underground, and to procure for the citizens the best system at the lowest cost. The amendment was lost. Mr. Clay then moved an amendment that the minutes be confirmed, with the exception of the one relating to the telephone wires. He pointed out that when a report had been received from the paving department about the condition of the streets, Mr. Southern's proposal to form a special committee might come on. The amendment was carried.

Sir James Anderson.—Before the reading of Mr. W. B. Sayers's Paper at the Institution of Electrical Engineers last night, the President, Mr. W. H. Preece, referred to the death of Sir James Anderson in the following terms:—"My first task is, perhaps, one of the most unfortunate and disagreeable that a President of an Institution of this kind can possibly have to discharge. It is to allude to the effects which Time inflicts on all communities when his scythe sweeps round and about and amongst us. We have had to-night announced to us the death of three prominent members of this Institution, but there is one who has gone to his long rest that many of us knew intimately and knew well, and whose loss will be very severely felt by a very large class of the members of this Institution. I refer to Sir James Anderson. Sir James Anderson is a man whom I have known intimately for now nearly thirty years. As a man I have never met anybody who more obviously carried in his face the characteristic of pure manliness, and whether you met him as an officer on the bridge of a ship when he was a distinguished captain in the Cunard service; or whether you met him on that gigantic vessel the 'Great Eastern,' when he successfully laid the cables across the Atlantic; or whether you met him as a Director of the Company which he managed so well; or whether he appeared amongst us here, he was one of those men who, somehow or other, succeeded in winding himself round your heart, and you felt that in him you had a friend and a strong man. In addition to this he was essentially a gentleman, and I am sure those members of the Eastern Telegraph Company and all its associated companies who have acted in various capacities under him will say they could never wish to have a chief who looked after their interests, who carried their secrets, or who attended to their wants more honestly and faithfully than Sir James Anderson. The Council to-night have desired that a vote of condolence should be sent to his son as his representative, and I am quite sure I am only echoing the wishes of all the members of this Institution when I say they heartily join in doing this deed of sympathy and this act of reminiscence of the services we have received from Sir James Anderson."

ELECTRICITY AS A MOTIVE POWER.*

BY ALBION T. SNELL.

(*Continued from page 739, Vol. XXX.*)

§ 10. Calculation of the Field Excitation.

(*a*) The following points have now been determined:—The size of armature, the gauge of wire, and the number of turns for its winding; the shape of field-magnets, and length of the winding space; the bore of polar cavity and the width of the poles; the magnetic flux and the densities in armature, gap, field cores and yokes.

The excitation necessary to give these fluxes and the corresponding winding have now to be calculated. The method adopted by the author does not take into direct consideration the permeability of the iron, although, of course, this is understood in the limiting values of B proposed. It is based on curves, see Plate I., connecting induction per square inch of core with ampere turns per linear inch of distance through which the induction has to be maintained. The principle of these curves was first suggested by the Hopkinsons in 1885. The co-ordinates are the mean values of the ascending and descending curves of the magnetisation. The variation of induction due to hysteresis is most marked with cast iron, but is of little importance with well annealed Swedish plates, such as are used for armature cores, especially if the induction be about B = 100,000. Therefore in practice no trouble is caused by hysteresis other than the loss of energy due to the cyclic change of magnetism, which is rendered evident by a development of heat. The calculation for this will be given further on.

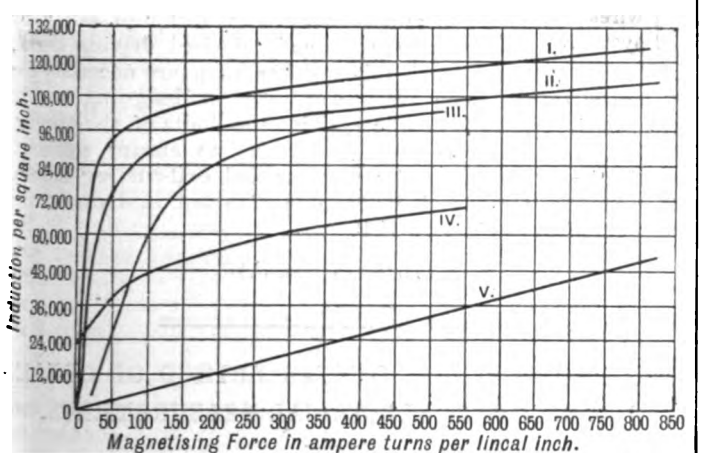

PLATE I.—Curves of Magnetic Induction in Iron and Air.

Scale of Ampere Turns for Iron: One division = 50 ampere turns per inch.
I. Annealed Swedish Charcoal Plates, as used for Armatures.
II. Wrought Iron Forgings, as used for Field Magnets.
III. Cast Steel, as used for Field Magnets.
IV. Cast Iron, as used for Field Magnets.
V. Air—To read Ampere Turns multiply abscissæ by 20.
All the Readings have been determined from the Mean of the Ascending and Descending Curves of Magnetisation.

In Plate I., Curve I. refers to annealed charcoal iron plates, from 22 to 24 B.W.G., the data are taken from experiments made by Mr. George Halliday.

Curve II. relates to magnet iron, large scrap hammered, allowed to cool slowly after forging. The values of the co-ordinates were originally taken from Dr. Hopkinson's paper on the characteristics of the dynamo; but they have been altered to suit the samples of iron used by the author, most of which have been supplied from Yorkshire forges.

Curve III. is taken from the recent experiments of Mr. Steinmetz with annealed cast steel, which is likely to be largely used for magnets.

Curve IV. is for the class of grey cast-iron generally supplied in London for magnets. The samples which have recently come under the author's notice have perhaps a slightly higher permeability than that implied in this curve. However, it is best to be on the safe side with cast iron, as the cooling so largely affects the results, and with these values there will be no doubt about the output of the machine.

* All rights reserved.

Curve V. shows the number of ampere turns required to send the induction through the gap. Its abscissæ are calculated from the equation

$$B''_g = \frac{AT}{0{\cdot}31328 \cdot \delta} \quad . \quad . \quad . \quad . \quad . \quad . \quad (11)$$

where $\delta = 1$ inch, and 0·31328 is a dimensional coefficient to convert the absolute measures into practical units, and also containing a factor to allow for the fringe of magnetism at the edges of the poles.

To use this curve find the ampere-turns corresponding to the density, and multiply by twice the length of the gap expressed in decimals of an inch.

(*b*) *Excitation for Open Circuit.*—The data must now be collected in order to make the calculations for the number of ampere-turns. It is necessary to know for the armature:—

B''_a = The induction per unit area.
$A_a 0{\cdot}85$ = The area of cross section less 15 per cent., which will be occupied by the insulating material between the plates.
m_a = Mean length of magnetic path in armature core.

For the gap:—

B''_g = The induction per unit area.
δ = Length of the air gap on one side.
A_g = Area of one of the polar cavities.

For the field-magnets:—

B''_f = The induction per unit area.
A_f = Area of core (wrought) in square inches.
A_{f1} = Area of yoke (cast) in square inches.
m_f = Mean length of magnetic path in cores and pole-pieces.
m_{f1} = Mean length of magnetic path in yoke.

Since the design is symmetrical about the perpendicular line *a b* (*see* Figs. 1 and 4), it is only necessary to measure the path of the lines of force around one-half of the circuit. The excitation thus determined refers to one limb only, and must be doubled to give the full number of ampere turns. This method is usually adopted because it both saves time and gives smaller figures.

The excitation for the several parts of the circuit is:—

Armature:—	$m_a f(B_a'')$.
Field cores:—	$m_f f(B_f'')$.
Field yoke:—	$m_{f1} f(B_{f1}'')$.
Gap:—	$2\,\delta f(B_g'')$.

And, summing up—

$$A.T_s = m_a f(B_a'') + m_f f(B_f'') + m_{f1} f(B_{f1}'') + 2\,\delta f(B_g''). \quad (12)$$

(*c*) *Excitation to be added at Full Load.*—In the preceding equation the demagnetising effect of the armature is neglected, and no allowance is made for the fall of potential over the internal resistance of the armature and series coils.

The demagnetising and cross-magnetising fields due to the armature have been already referred to, and it has been shown that these effects are most pronounced with the gramme type of armature. The subject has been exhaustively treated during the past two years, and need not be discussed in detail here. Suffice it to say, that the band of conductors lying between the pole tips will, as a whole, tend to produce a field in the opposite direction to that due to the main excitation; while the coils lying under the pole-pieces, *i.e.*, in the polar cavity, will tend to cause a cross magnetism. The latter is not of serious importance if the pole-pieces be very thin near the centre, as at *a* and *b* in Figs. 4 and 6. If, however, the pole-pieces be very massive in the region of the centre line there will be a cross field, which will have a tendency to twist the main field by crowding out some of the forward induction. But this can be almost entirely obviated with the relative proportions and shapes of magnets given in § 8.

The demagnetising turns are of more importance, and must be allowed for by an equal forward induction. The disturbance is, with gramme rings, proportional to the armature current multiplied into the number of turns included in the angle of lead; and this product must be multiplied by the coefficient of leakage between the field and armature, since a certain quantity of the field induction is lost in space.

Digitized by Google

Therefore the compensating turns are

$$C.T_s = C_a \frac{2\theta}{360} i_a v = C_a \frac{\theta}{180} i_a v \quad . \quad . \quad (13)$$

where θ = the angle of lead in degrees.

With drum armatures the disturbance is about one-half as great, and so the compensating turns are

$$C.T_s = C_a \frac{\theta}{180^\circ} \frac{i_a v}{2} . \quad . \quad . \quad . \quad . \quad (14)$$

To find the turns to compensate for the fall of potential, it is necessary to make two calculations for the $A.T_s$, one with no current flowing in the main circuit, and hence no armature reactions, and one at full load. The former will determine the strength of the shunt coils if the machine be compound wound; and the latter will give the shunt excitation plus extra turns to be added for the fall of potential due to the internal resistance. The total excitation is :—

$A.T_s$ for open circuit + $C.T_s$ for demagnetising effects + $C.T_s$ for fall of potential.

Practically, with large gramme rings the two last quantities will be about one-third of the first.

If the machine be shunt wound the winding must be determined at full load, and the $C.T_s$ must be added before calculating the gauge of wire.

The same remark also applies to a series machine.

A few trial windings will soon illustrate the point, and facility will come with experience.

§ 11. Special Points to be observed in designing Motors.

So far the author has considered the design of either dynamo or motor simply from the point of view of the total E.M.F. of the armature, and has given no special attention to the torque. But it was mentioned in § 2 that in designing motors it was essential to give due weight to both the maximum and average couples likely to obtain. The importance of this will be best seen from an inspection of the equation for the torque in terms of the armature constants :—

$$\text{Torque} = T = \frac{C_a i_a}{2} \cdot \frac{N_a}{K}, \quad . \quad . \quad . \quad . \quad . \quad (15)$$

or the torque is directly proportional to the product of the number of turns of wire, the magnetic flux, and half the armature current. K is simply a dimensional coefficient. The numerical value of K is $852{\cdot}3 \times 10^6$, if T be in pound feet, so that adopting the practical unit

$$T = \frac{C_a i_a N_a}{852{\cdot}3 \times 10^6} \text{ pound feet.} \quad . \quad . \quad . \quad (16)$$

Now, in all ordinary motors the number of turns of wire in the armature, C_a, is constant, and only the current i_a, and the magnetic flux N_a vary. There are two simple cases for consideration in practice. First, when both i_a and N_a vary; this occurs with a series-wound motor, and it should be noticed that a relatively small increment of current may cause a considerable increase in the value of the torque, for the magnetism will be greatly varied at the straight part of the characteristic with low values of B, and therefore N_a will at this point increase much more rapidly than i_a; whilst after the knee of the curve is passed the rate of increase of N_a for increments of i_a will slowly decrease, until a point is reached where the torque simply varies with the current.

The second case is where N_a is constant, and i_a alone varies. This condition is given with a shunt-wound motor, if it be assumed that the armature reactions are negligible. The torque, therefore, will simply vary with the armature current; it will be a minimum with small loads, but will finally attain the same maximum value as it would if the motor were series-wound. Both of these windings give special advantages to a motor, and hence they are severally selected for particular work. The compound-wound motor is a combination of the two schemes, and has not met with much favour as yet. The uses of the three types of windings will be more fully discussed further on.

It remains now to investigate the best lines for building armatures for special turning-moments.

If the desired brake horse-power and the speed of the motor be known, the work per revolution and the torque can be easily determined.

The work per revolution in foot pounds

$$= \frac{\text{B.H.P. } 33000}{n} \text{ foot pounds} \quad . \quad . \quad . \quad (17)$$

and the torque $T = \frac{\text{B.H.P. } 33000}{2\pi n}$ pound feet, . . . (18)

n = revolutions per minute.

It should be noticed that T is independent of the diameter of the armature.

The peripheral pull exerted by the armature

$$= \frac{\text{B.H.P. } 33000}{2\pi n} \cdot \frac{1}{g} \text{ pounds} \quad . \quad . \quad . \quad (19)$$

where g = the radius of the armature in feet.

This force will act tangentially on the winding, *practically* at two parts diametrically opposite each other, and just underneath the leading horns of the pole-pieces. If the value represented by B.H.P. be the average load, we can thus determine the average strain on the wire; and if it equal the maximum output the maximum *running* torque is known. But suppose the current to fluctuate largely, and at times to exceed the current corresponding to the maximum current output; at starting, for example, the momentary rush of current may easily be twice or even three times as great. Then, from what has been said, it is clear that the torque will be increased also and it may be sufficiently to endanger the stability of the winding, or even to bend the shaft. Therefore, in motors it is usual to allow a very large factor of safety by supporting the winding by specially devised driving horns, and by the use of much stiffer shafts than are necessary for dynamos of the same average output. In designing motors, then, it is advisable first to examine the limits of the turning couple, and then to take precautions to ensure sufficient mechanical strength. For tramcar and coal-cutting motors it is usual to provide shafts from 2½in. to 3in. in diameter for outputs of from 15 to 20 H.P.

(To be continued.)

CROMPTON'S POTENTIOMETER METHOD OF OBTAINING ACCURATE ELECTRICAL MEASUREMENTS.

To meet the requirements of Municipal authorities, standardising laboratories, manufacturing engineers, and others who desire to have a complete system of electrical measuring apparatus capable of making electrical measurements to a high degree of accuracy, Messrs. Cromptons have during the last six years been engaged in perfecting what is known as the potentiometer method.

As is well known, this method consists in reducing any of the three electrical quantities which are to be measured to the form of electrical pressure, or E.M.F., so that it can be compared by means of a potentiometer with a standard pressure such as that of the Clark cell.

The potentiometer itself is shown diagrammatically in Fig. 1. It consists of a wire A B stretched over a frame. Up to quite recently this wire was made of an alloy of platinum and iridium made as hard as possible to reduce wear. It was necessary to take great pains to ensure that this alloy was well mixed, and that the wire was accurately drawn in order that the electrical resistance per unit of length might be constant. The instrument is used in the following manner:—A constant current is maintained in the wire A B from one or more secondary cells of sufficient size to keep it fairly constant for three or four days' working. A variable resistance or rheostat is introduced in series with the cell and wire, arranged so as to adjust this current to give a certain difference of potential at the two ends of the wire. The circuit which includes the E.M.F. to be measured is connected at one end to one terminal, A, of the slide wire, and through a galvanometer to a sliding saddle C,

Digitized by Google

which carries a knife edge to make contact on the wire A B at any desired point of its length. This circuit is so coupled up that the E.M.F. to be measured is opposed to the E.M.F. in the portion of the slide wire A C, in order that the position of C on the slide wire can be adjusted until the two E.M.F.'s balance one another so that no current passes through the galvanometer. In order to compare the E.M.F. to be measured with the standard E.M.F., a Clark cell is put in in circuit with the galvanometer, and the position of the slide C is noted when the above-mentioned balance has been obtained. The electrical pressure or E.M.F., required to be compared is then substituted for the Clark cell, and a similar balance found by adjusting the slider C a second time. Then the comparison between the two E.M.F.'s can be made by comparing the respective lengths of the slide wire included between the points A and C in the first and second case. By dividing the slide wire A B into a suitable number of parts, and adjusting the variable resistance until the galvanometer comes to zero when the Clark cell is in circuit and the contact C is at a point on the scale corresponding to the temperature value of the Clark cell, say 1·434 at 15°C., the instrument becomes direct reading in volts or fractions of volts.

The apparatus forming such a set consists of—1. A set of standard Clark cells; 2. The comparing instrument which is called the potentiometer; 3. A set of fractional resistances which can be used to reduce the pressures to be measured to that which can be conveniently compared by the potentiometer.

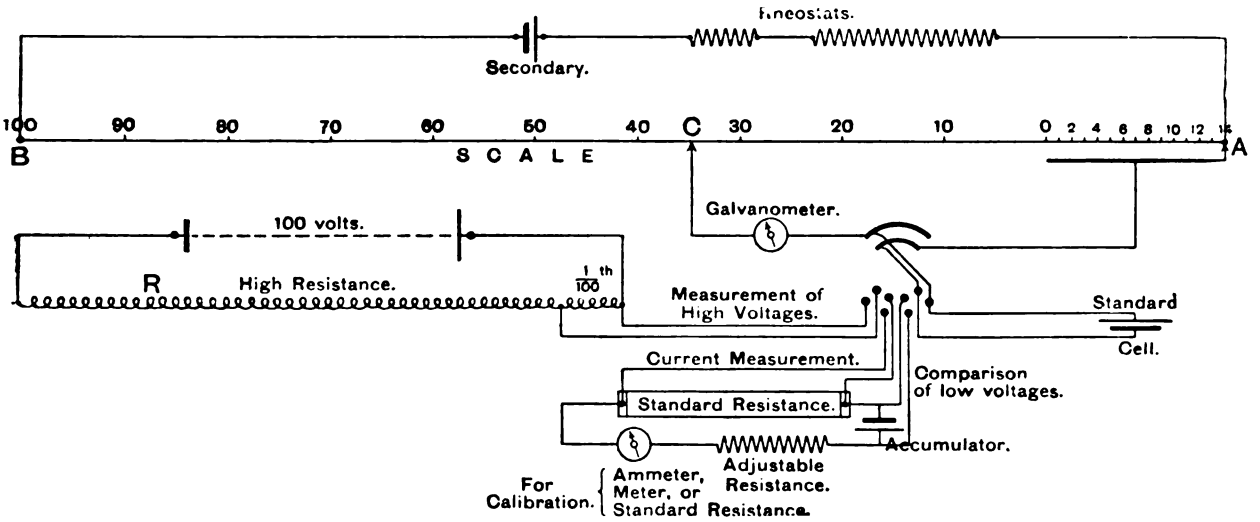

FIG. 1.

Dr. Fleming in the year 1883 first called Mr. Crompton's attention to the advantages of this system of measuring. Since that time the system has been steadily developed, and successive refinements have been introduced into the various instruments which will now be described. As the following description will apply to a set of instruments such as are suitable for a municipal standardising laboratory, it is here necessary to specify what are the requirements and limits of accuracy within which these instruments may be reasonably expected to measure. First, comes the verification of voltmeters. This is of importance on account of the disputes that are likely to arise as to the pressure supplied from electric-lighting stations. Voltmeters for standard pressures of 50 to 100 and 110 volts, are principally used for noting the pressures in the consumers' houses, and for such cases it is desirable that their readings at about the standard pressure should be verified to one-tenth of a volt or within one part in 1,000. Next it should be possible to verify and certify the constant of the various kinds of meters by which the electrical supply is measured to the consumers. These also ought to be verified to one part in 1,000. Next comes the verification of ordinary ammeters or current instruments used for trade purposes to about the same degree of accuracy. In both these last cases the range through which instruments would have to be compared is very considerable; for instance, the instruments sent for verification may be those used for testing electric lamps or for telegraphic purposes, measuring currents of one milliampere, up to those used for metallurgical or electrolytic purposes up to 5,000 amperes, or more.

The correct comparison of resistance standards as well as the correctness of the ratios of resistance boxes ought to be capable of verification to one part in 10,000.

In the comparison of resistances must be included the testing of the conductivity of various metals and the insulation resistance of various insulating materials.

The latest form of potentiometer which we now describe and illustrate has a scale 25in. long divided into 1,000 parts. The standard wire stretched over this scale is one-fifteenth part of the whole wire, therefore each division on the scale being one-fortieth of an inch repesents one fifteen-thousandth of the pressure at the two ends of the wire; in other words, if, as is generally the case, the instrument is standarised to 1·5 volts at the terminals of its wire, each division of the scale represents one ten-thousandth part of the volt.

In the first form of instrument proposed by Dr. Fleming, the potentiometer wire was made of an alloy of platino-iridium four metres long and had a resistance of about 20 ohms. The wire was divided into two parts and stretched over a scale; the whole of the wire, being required for measuring purposes, had to be carefully calibrated, that is to say its electrical resistance made equal per unit length throughout its entire length. This was a very tedious and expensive process. It was found very difficult, if not impossible, to obtain wire as it finally left the drawplate which was sufficiently homogeneous to be used without further adjustment. In most cases the whole of the wire had to be carefully scraped or rubbed until the required equality of resistance was obtained. Such a wire was very valuable, and if it was broken or accidentally melted, its loss was a serious matter.

In their latest form of instrument (Fig. 2) Messrs. Cromptons have abandoned the use of this expensive material, and at the same time have arranged so that only one-fifteenth part of the wire A B is stretched over the scale and subject to the wear of working. A B in the drawing shows this portion of the wire 25in. long, stretched over a scale divided into 1,000 parts. The resistance of this wire is usually about 2 ohms, and the remaining wire is divided into 14 coils, each of about 2 ohms, so that the R of the whole is 30 ohms. These coils are naked spirals, the terminals of which are fixed to the underside of the 14 contact blocks shown at E. The swinging arm shown can make contact with any one of these blocks. It is an easy matter to adjust these 14 coils when the instrument is first made so that their R will accurately equal one another, and the resistance of the working wire A B can then be adjusted by slightly stretching it until it is also exactly equal to any of them. As the 14 coils are protected they never need further adjustment, but if in the course of time the exposed portion of the wire A B becomes worn or is in any way damaged, a new piece of wire can be substituted in a few minutes and stretched, by means of the

Digitized by Google

stretching screw shown at F, until its resistance over the portion from 0 to 100 exactly balances that of any one of the 14 coils. C is the sliding saddle carrying the contact. This consists of an ebonite box with dovetailed slides arranged to slide smoothly on the scale. It is provided with a knife-edge spring contact so that the contact must be made with a regular pressure which is independent of the pressure of the hand of the user; it also has a micrometer adjustment for accurate work. The semi-circular switch G and the cylindrical rheostat G 1 shown to the left, form part of the variable resistances above described and which are required to reduce the difference of potential between the terminals of the wire to any desired value. The value that has

Digitized by Google

been chosen in this instrument is 1·5 volts. In order to obtain this, one small accumulator cell is connected to the left hand pair of terminals, and the resistances attached to G and G 1 are adjusted until when the knife-edge contact is put down at the value of the Clark cell, say at 15° C., 1434, the galvanometer comes to zero. In the present instance this reading is obtained by putting the swinging arm E on to the 14th block, and putting down the knife edge of C at 34 on the scale. When such a balance is obtained every one of the scale divisions will be equal to one ten-thousandth of a volt. The instrument is provided with 4 pairs of terminals, 1, 2, 3, 4. A Clark cell can be put on to one of these, and any three other electrical pressures to be measured can be connected on to the others. The switching arrangement H shown in the centre brings the galvanometer into series circuit with any one of these pairs of terminals. The contact key K shown to the extreme right is used for short-circuiting the galvanometer.

The fractional resistances for the measurement of high voltages shown at R in Fig. 1, require no special mention further than that, whenever it is required to measure an electrical pressure greater than that on the terminals of the potentiometer, that is to say in this case greater than 1·5 volts, the pressure to be measured is applied to certain terminals of a resistance box, and the terminals of the potentiometer are connected to other terminals on this box which include between them a resistance which is an even part, say, one-tenth, one-hundredth, or one-thousandth of the entire resistance of the box.

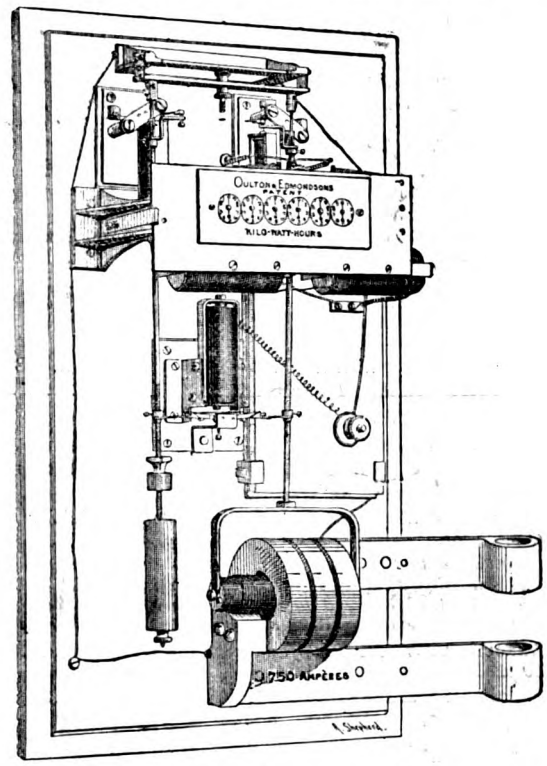
When, however, the potentiometer is employed for measuring currents, this is done by measuring the difference of pressure at two points on standard resistances which, in order to make the instrument direct-reading, must be either one ohm, one-tenth, one-hundredth, or one-thousandth, and so on. As these low resistances have to carry very high currents, they have to be designed so that they do not heat to a sufficient extent to introduce errors.

Figs. 3 and 4 represent a form of water-cooled resistance which has given excellent results. This consists of a cylindrical vessel made of brass into which a resistance made of manganin sheet S R is made in such a manner as to form a diaphragm dividing it into two parts. This manganin sheet is carefully protected by an insulating material and the cylinder is filled with water, and the circulation is provided by means of the pipes P. The water circulates down one side and up the other side of the diaphragm and its temperature is thus easily prevented from rising to a sufficient extent to alter the resistance of the manganin sheet to the extent of one part in 10,000. The manganin sheet is provided with massive copper terminals as shown, the terminals of the potential leads being taken off at the point P P. A resistance that is capable of measuring currents up to 2,000 or even 3,000 amperes is easily contained in a cylinder about 10in. diameter by 18in. high.

THE OULTON-EDMONDSON METER.

The ingenious and highly-promising meter which was brought out under this title some years ago offered several improvements over the Aron meter, of which it was a modification. There was a single clock movement, and two slow-torsion pendulums. As in the meter which we described last week, but by an independent invention, a gravity impulse arrangement has been introduced to drive the pendulums, instead of a clock escapement. A small-impulse arm which is not clearly visible in the illustration, acts upon a cranked arm projecting from the pendulum. The impulse arm is lifted by an electro-magnet, and is allowed to drop on the pendulum at the right moment. The lifting electro-magnet is controlled by the pendulum. All friction is thus eliminated, and excellent time-keeping qualities are ensured. A difficulty in such meters has been the synchronism of the two pendulums when no current is passing. Dr. Aron has hung a small weight on a very slack thread, which was sufficient, when there was only a small tendency to vibrate at different periods, to keep the pendulums in unison. In the present meter a device is introduced for the same purpose. It will be noticed that the pendulums are hung from a bar which is suspended by stiff springs. This bar receives an extremely small horizontal motion which is sufficient to keep the pendulums in unison, unless a certain definite force is exerted to make the meter work in the usual way by recording the difference between the number of beats of the two pendulums. As in the meter which we described last week, a catch arrangement is provided for stopping the meter. When no current is passing, a magnet, shown in the middle illustration, affects this by means of two hooks, which engage with the pendulums when they are swinging inwards. The hooks themselves make a path for the current, and by short circuiting a resistance, cause the initial current which starts the meter to be rather larger than normal.

It appears, however, from the description which has been sent us, that it is only when the meter is cut off altogether from the supply that the pendulums are stopped. To be of value, the stopping should be determined by the cessation of the main current. An important feature of the original Oulton-Edmondson meter is retained in this one; the two currents passing through the main coil and the volt coil would not, *by themselves*, give proportional readings, for the force required to produce the vibrations of a pendulum is in proportion to the square of the number of vibrations.



Upon each volt coil, therefore, there is wound a "correcting coil," carrying a very small proportion of the current passing into consumption. This small current makes the reading proportional throughout any range. The sparking at the contacts of the impulse gear is prevented by the use of a condenser and a resistance.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, May 12th.

PHYSICAL SOCIETY.

5 p.m. Papers to be read: (1) "The Drawing of Curves from their Curvature," by C. V. Boys, F.R.S. (2) "The Foundations of Dynamics," by Dr. Oliver Lodge, F.R.S.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Isoperimetrical Problems," by Lord Kelvin, P.R.S.

TUESDAY, May 16th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be read and discussed: "Wreck-raising in the River Thames," by C. J. More, M.Inst.C.E. At this meeting the final ballot for members for the session, and the last of the present series of receptions by the President and Council, will take place.

WEDNESDAY, May 17th.

ROYAL METEOROLOGICAL SOCIETY.

7 p.m. Ordinary Meeting at the Institution of Civil Engineers.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Paper to be read: "Composite Heliochromy," by F. E. Ives.

ROYAL MICROSCOPICAL SOCIETY.

8 p.m Meeting at 20, Hanover-square, W. Exhibition with the Projection Microscope, by Sir David Salomons.

THURSDAY, May 18th.

CHEMICAL SOCIETY.

8 p.m. Paper to be read: "Observations on the Production of Ozone during Electric Discharge through Oxygen," by W. A. Shenstone and M. Priest.

SPECIAL NOTICE.

With this issue of "THE ELECTRICIAN" is published a Steel-Plate Portrait of the Late SIR JAMES ANDERSON.

Complaints of non-receipt should be at once sent to the Publisher.

STEEL-PLATE PORTRAITS

Of Willoughby Smith; W. H. Preece, F.R.S. (President of the Institution of Electrical Engineers); Michael Faraday; Sir John Pender, G.C.M.G., M.P.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Patey, C.B.; Dr. John Hopkinson, F.R.S.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz; Prof. W. E. Ayrton; Lord Rayleigh, F.R.S.; Cyrus W. Field; Werner von Siemens; and Sir James Anderson, have been issued as Supplements to "THE ELECTRICIAN."

Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price 4s. 6d., carriage paid (U.K.).

THE PUPIL SYSTEM.

One of the avowed aims of technical education is to radically modify the old "premium pupil" system, and one or two recent cases in the law courts will also do something towards furthering that object. Some eighteen months ago we recorded, and commented upon, a case in which £120 damages were awarded to a pupil's parent owing to failure on the part of an electrical engineering firm to *instruct* the aforesaid pupil, who had paid a premium of £150. In the action *Cridlan and another* v. *Marler and Bennett* reported in *The Times* of Tuesday, exactly the same point was at issue, and exactly the same decision, this time with £125 damages, was arrived at. The complaint was that the pupil, who had paid £200 premium and bound himself for three years, had been kept for half that time at mere routine work and drudgery, no opportunity being given him to learn the technique of the business, which was that of auctioneer and house-agent, and no attempt being made to instruct him. The defendants replied that the ordinary custom was followed, and that "they could not always be at their pupils' elbows and delivering lectures to them." Large sums of money ought not to be taken, and as a matter of fact are not taken by firms of standing, without it is thoroughly understood that the sole *quid pro quo* is merely the opportunity of "picking up" practical knowledge; and if the pupil has had a good grounding in science at school or college, and is able and willing to learn, there is no call for animadversion. It is the practice of taking on an unlimited

Digitized by Google

throng of raw youths and exacting heavy premiums from unsuspecting parents that we are glad to see exposed in the law courts. In the case of *Cridlan* v. *Marler and Bennett*, there was no question of bad faith but of difference of opinion as to what was a fair return for a large premium. The pupil seems to have been engaged in learning the useful but not intellectual work of an office-boy. The jury settled the dispute, and the judge remarked that it was a very delicate question and he was very glad that he had not got to decide it himself. In the other case to which we have alluded, it was proved that only seven or eight workmen were employed and about sixty-five premium pupils were taken; the pupils, in fact, were simply made use of as a particularly cheap, if not high-class, kind of labour.

The old system of indentures of apprenticeship promises to die out, like the old trade guilds. The modern agreements are far less formal, and the ancient customs and laws which defined the relations of an apprentice to his master can hardly be said to apply to them. Most engineering firms who take pupils will confess, if pressed, that they do not pretend to teach, or to do much more than give facilities for learning the practical work of the different departments. When the course was spread over five or seven years there was time to take in the practical details and reflect on the principles which underlie them, and to develop some of that instinct which was so characteristic of the engineer of the old school. A pupil who comes to a factory having an elementary acquaintance with mechanical science has only to keep his eyes open to learn how the principles are applied. At the same time he acquires a knowledge of the use of tools, which is necessary for the proper appreciation of good workmanship, and is the only way of becoming intimately acquainted with machine construction. The tendency to shorten the course to less than two years is to be regretted. Two years may be enough for a smattering in each department, but it is hardly long enough to give a chance of seeing a considerable variety of work. A firm specialising in one or two particular lines may offer little or no variety, one year's work being like that of another; but such firms should be avoided; even if the pupils really receive instruction they will be fitted for only one particular branch. Every year shows that the tendency to specialise is becoming more pronounced, and, no doubt, there are many cases in which a lad is compelled to begin to earn a living at the earliest possible date. But this should not affect the general character of the training of those who wish to enter so important a profession as that of electrical engineering. We are inclined to doubt whether most lads, even after going through a year or so of scientific study, are capable of making a well-considered selection of electrical engineering as their future profession. Medical men do not enter for their "first M. B." with the distinct aim of becoming specialists in some particular line; the selection, if made intelligently, must be made after the qualifying training has been completed. An intelligent desire to become an engineer is easy to understand; but before he knows anything of engineering how can a student choose a special branch, unless tempted to do so by the popular cry that electrical engineering is in its infancy and is the "coming thing?"

The ideal course is two years of science (real science not "technical education"), after which a choice between mechanical and civil engineering may be made; two or three years at a large general engineering works, if mechanical engineering be selected, and then one or two years at electrical works if electrical engineering be finally chosen. Partly because the necessity for preliminary scientific training has arisen, and partly because many lads have no opportunity for such an ideal course, technical education is offered, and tends, as we have said, to radically modify the apprentice system. Technical education can do nothing but teach principles; it cannot give a training in a profession, for it can give no practical professional experience worth mentioning. Pupilage in works, on the other hand, can seldom do more than offer free opportunity of picking up practical experience; it can give no actual teaching worth mentioning. The free run, or even a run under rules and restrictions, of a large factory is a most valuable privilege, and is well worth a handsome premium. Pupils are, however, as a rule, an unmitigated nuisance, and engineering firms are justified, we think, in raising their premiums to five hundred guineas if a few pupils will insist on paying it. Considering the work they may spoil, the dicipline they may disturb, the information about prices and standard designs which they may pick up, and the possibility of their setting up on their own account in direct competition with their late masters, the one hundred pounds a year which many electrical firms ask is little enough—from the masters' point of view,—for the pupils, *caveat emptor*. Though some decline them at any price, there are still plenty of first-rate firms who will take pupils. Because advertisements or circulars may mislead, the system need not be blamed.

The results which are likely to accrue, if the system of pupilage at works is abandoned or seriously cut down, are well illustrated in the remarks made by Sir Benjamin Baker at a discussion at the Institution of Civil Engineers. These remarks, which we print elsewhere, were made by a man whom no one can for a moment charge with contempt of theory, and one whose works have been the outcome of most arduous calculation. The practice of mechanical and of civil engineering is well established on a sure foundation of half a century of experience, and a careful engineer will consult previous cases as a guide for intended works. In electrical engineeering the ten years of its history affords but little solid experience of this kind. A few facts are occasionally collected into a Paper which is read before some society, and there gets picked to pieces by rival firms or theorists. The enquiring student after spending the day in a foundry or at the vice, comes to learn, and goes away unable to say what "the practice" is in connection with the subject he has heard discussed. No wonder that he seeks an apparently sure guide in the formulæ with which he filled his note books in his lecture-room days. Amongst other matter of great interest and importance in Dr. W. Anderson's "Forrest Lecture," of which we commence an abstract in another column, some observations will be found on the training of young engineers. He, too, while dwelling on the value of a preliminary scientific training, does not lose sight of the practical training which is so essential to the qualifications of an engineer. He recognises that there is a tendency for the pendulum to swing the other way, and for the rising generation of engineers to wax conceited and to imagine that scientific study will enable them to commence professional work at once, without going through the practical training which is afforded by the system of pupilage or apprenticeship.

The technical college and the workshop being, as we have pointed out above, complements the one of the other, it will be a matter for grave regret if any more of our leading firms, (at whose works alone proper training can be acquired), with the danger of adverse legal decisions superadded to the general nuisance of pupils, should come to the conclusion that the game is not worth the candle and decline to take in pupils at any price. The best course in the interests of the industry would be to insist on a precise agreement, setting forth in plain English that the firm does not pretend, and does not intend, to teach.

SIR JAMES ANDERSON.

We deeply regret to record the death of Sir James Anderson, which took place at his residence in London on Sunday last, the 7th inst., after an illness of nearly three months' duration.

Sir James Anderson was born at Dumfries in 1824, and joined the Merchant Navy at the age of sixteen. In 1851 he entered the service of the Cunard Company, and commanded some of their best ships. He was a successful captain and navigator.

When the Telegraph Construction and Maintenance Company was formed for the purpose of laying the second Atlantic cable, the first having been irretrievably lost, the "Great Eastern" steamship was chartered to do the work, and it became a question as to who should command that ship. The then Chairman, Mr. (now Sir John) Pender wrote to Mr. McIver, the manager of the Cunard Company, asking him to grant the Company the loan of one of their best and most efficient captains. Mr. McIver kindly consented, and named Captain Anderson. This was his introduction to the Submarine Telegraph System, then in its earliest stage.

In the first voyage of the "Great Eastern," the cable parted, and Captain Anderson attempted to pick it up. He found, however, that the machinery at his disposal was not equal to the work, but felt confident that with proper appliances he could pick up the cable from the great depths of the Atlantic.

On the return of the ship Captain Anderson so impressed the Directors of the Telegraph Construction Company with his views, that they individually largely subscribed to the necessary capital, and the Board determined not only that the ship should be sent out to recover the cable that was lost, but also that a second cable should be laid, if they could find the amount of money necessary to enable them to have one manufactured. In both of these projects they were entirely successful. The ship went to sea under Captain Anderson's command, laid the new cable, and picked up the cable broken the previous year. For carrying out this important operation Captain Anderson received the honour of knighthood.

The fact that cables could be picked up from such great depths and repaired gave a wonderful impulse to submarine telegraphy. Sir James Anderson saw that there was a great future for it, and from that time he identified himself with the small band of men, led by Sir John Pender, who have been the real pioneers of submarine telegraphy, and who have carried out that great system which now extends to all parts of the civilised world.

At the time of his death Sir James Anderson was Managing Director of the Eastern Telegraph Company, the Eastern and South African Telegraph Company, and the West African Telegraph Company; he was Chairman of the Brazilian Submarine and Direct Spanish Telegraph Companies, and a Director of the Anglo-American, the African Direct, the Eastern Extension and the West India and Panama Telegraph Companies, and a Trustee of the Globe Telegraph and Trust Company. He was also a Director of the Metropolitan Electric Supply Company.

Sir James Anderson had a strong literary tendency, and was a member of the Statistical Society, before whom he read a Paper on "Statistics of Telegraphy," afterwards publishing a treatise under the same title which is regarded as a text-book on the subject. He was the author of important Papers on "Cables in Time of War," "The Government Purchase of Submarine Cables and Reduction of Telegraph Rates," "The Telegraphic Communication of the Empire and a Comparison of the Various Routes to the East." Sir James took part in the International Telegraph Conferences at Rome, St. Petersburg, London, Berlin, and Paris, and long advocated an "Authorised Vocabulary" from which the words used in code messages should be taken. It was due to his efforts in this direction that the last Conference decided to compile an official list of words, which is nearing completion. Sir James was a J.P. for Dumfrieshire, F.R.G.S., F.G.S., F.S.S., and received many distinctions from foreign Sovereigns, including those of Italy, Spain, Greece, and Turkey.

In all matters affecting the well-being of the staff of the Telegraph Companies in all parts of the world he always evinced a deep interest, and one of his latest acts was to support the establishment of a staff pension fund, the success of which has now been established; and its formation by Sir John Pender and Sir James Anderson will be long remembered with gratitude.

Sir James Anderson also took an active interest in *The Electrician*, of which he was one of the proprietors.

It can be said of Sir James Anderson that he endeared himself to all who came in contact with him. Endowed with a large measure of sterling common sense, of genial presence, possessed of the utmost kindness of heart, and availing himself of unnumbered opportunities of doing good to many besides those who had the honour of serving under him, he will be long remembered with very sincere affection and respect.

> "Whatever record leap to light,
> He never shall be shamed."

Almost his last public appearance was to take the chair at a dinner in aid of the Royal Alfred Home for Aged Seamen, on which occasion an unusually large sum of money was, through his exertions, subscribed. His name was greatly respected in the City, and his colleagues, with whom most harmonious relations prevailed, feel that they and the great cause of submarine telegraphy have sustained a severe loss, his intimate knowledge of the great cable network and his unique experience making him a most valuable colleague.

Sir James was twice married, and leaves one son, Mr. Kenneth Lockwood Morrison Anderson. Lady Anderson pre-deceased him in September, 1891.

On Tuesday last a funeral service took place at St. Philip's Church, Earl's Court-road, S.W., kindly lent for the occasion by the vicar, the Rev. W. Smale, M.A., who conducted the service, assisted by the Rev. Calmont Gallacher. A most impressive address was delivered by the Rev. H. W. Webb-Peploe, M.A. Many very old friends of the deceased were present, as were also the representatives of all the Telegraph and Cable Companies and the General Post Office. The coffin was covered with beautiful wreaths, and upon it was fixed a piece of the 1865 cable, in the recovery of which Sir James took so active a part.

The interment took place at Dumfries yesterday (Thursday). After a funeral service at Park House by the Rev. Mr. Chapman, at which a great number of Sir James's friends in Scotland were present, the body was removed to St. Mary's Churchyard, and the last rites were performed by the Rev. Mr. Paton. All the chief residents of the town and district were present at the graveside.

THE INTERDEPENDENCE OF ABSTRACT SCIENCE AND ENGINEERING.*

BY WILLIAM ANDERSON, F.R.S.

Before commencing the task which has been imposed upon me by our Secretary, I think it will be well to explain the origin of the "James Forrest Lectureship."

During the Session of 1889 the Council of the Institution determined to have a portrait of Mr. Forrest painted with the view of presenting it to the Institution. An excellent likeness was produced by Mr. Wm. M. Palin, and it was presented at the ordinary meeting of November 11, 1890. As soon as the members had seen the portrait a large number expressed a wish to have an engraving of it; a committee was formed outside the Council, funds were rapidly collected, and an excellent engraving, by Mr. James Faed, was produced and distributed, while the surplus fund, amounting to about £500, was placed at the disposal of the Secretary, who determined that it should be devoted to the establishment of a "James Forrest Lectureship," and that it should be administered by the governing body of the Institution for the time being, who would select the lecturer and determine the subject of his discourse.

This is the first lecture under the Trust. The high and undeserved honour of delivering it was imposed on me; I accepted the task with much hesitation and misgiving, being deeply conscious that I was incompetent to do justice to the occasion.

The theme which has been prescribed is "The Interdependence of Abstract Science and Engineering," and I imagine that the subject has been chosen because of an uneasy feeling which possesses many thoughtful men that this country is not keeping pace with its neighbours in engineering progress, and that we shall, in the future, have to pay more attention to abstract science and its application to practice than we have been, so far, in the habit of doing, if we are to come out victorious from the competition, ever increasing in keenness, which we meet with from abroad, and which our system of unrestricted trade tends so much to foster. It is impossible to visit the Continent of Europe, the United States of America, or even our own Colonies, without feeling conscious that, in many respects, their engineering works and their factories, to say nothing of their military and naval arsenals, exhibit the great advantages which have accrued from the employment of men of the highest scientific culture in the conduct of those enterprises—that the days are past when an engineer can acquit himself respectably by the aid of mother-wit alone, or of certain constructive instincts, which have been almost the only guides of engineers and manufacturers, even down to quite recent times.

This Institution has already shown, in the regulations not very long established with respect to the qualifications of the student class, that it is alive to the fact that some scientific training is desirable in a profession in which the lives of human beings, to say nothing of their property, are dependent on the knowledge and skill possessed; that in the vast works now undertaken a great deal more than intuition is necessary, and that scientific knowledge and training are attributes which the public have a right to demand of its engineers. So strongly does this feeling exist that it has assumed practical expression in the form of Science Colleges, which have been founded, either by individual liberality or by subscription, in every considerable town in the provinces, completely eclipsing London where the movement first began but where it languishes for want of adequate support, except, indeed, in the noble endowments of the City and Guilds schools, and the Government establishments at South Kensington.

The old arrangement must come to an end; we must not be deceived by our past experience, when, supported by our immense and exceptional natural advantages, it may be admitted that our rough system worked fairly well.

In those days, and the practice survives even now, a public schoolboy was taken into an engineer's office or into a factory, and there he exchanged his small store of dead languages for an equally slender equipment in science, acquired as it best could be while following the routine of his master's practice, the said master being himself but scantily provided with anything more tangible than experience, an endowment which, from its very nature, is incapable of being communicated fully and which can only be acquired by the professional activity of a lifetime.

It has often been my good fortune to discuss with Continental engineers the relative advantages of the English and foreign systems of training. The foreign engineer had, as a rule, an admiration for what he called our practical methods, and lamented that in his own country training was almost exclusively theoretical; but I think that the superior education of the operatives abroad was not sufficiently recognised—the managers, the foremen, the draughtsmen, and even to a great extent the mechanics and other operatives, had had the advantage of technical training even before they began to acquire mechanical dexterity, so that the want of practical knowledge of the leaders has been met by a fair amount of theoretical knowledge engrafted on the practical experience of the followers, and it is incontestible that this combination is producing results as advantageous to our foreign competitors as it is disastrous to our own industries.

With rare exceptions, in this country, has there been even a slender amount of theoretical knowledge imparted to the various grades of employment; it is only during the last few years that Science Colleges and technical education in schools and People's Palaces, are beginning to bring our operatives up to the level of our foreign friends, but, unfortunately, too late to retain that pre-eminence which we at one time could claim, and, I fear, placed too much confidence in; and, morever, a new danger has arisen in the circumstance that popular scientific education has taken a one-sided direction—that of mechanical or technical knowledge alone—so that, though the operative approaches his work with increased intelligence, he remains unfit to reason out the great economic problems on which his own welfare and that of the nation depend.

It is a matter of extreme surprise to me that so little attention is paid to the science of Political Economy, that not only the mass of the people, in whose hands the voting power now lies, but even, in a great measure, the representatives whom they elect have no systematic training in, and are grossly ignorant of, the principles which lie at the root of national prosperity. The further misfortune follows that politicians of the highest position do not scruple to trade on this ignorance, or to pursue a course which, in its consequences, is as bad—being ignorant themselves they strive to lead the ignorant, and set the operative against his employer and against society in general. The cheapness of newspapers, their wide diffusion, and their blind, not to say reckless, advocacy of popular fallacies acting on the ignorance, prejudices, and discomfort, if not suffering, of the operative classes are giving enormous power to trade organisations whose avowed object it is to improve the earnings and social standing of the operative at the expense of, or at any rate without regard to, the interests of every other class in the community; and this is to be accomplished not by encouraging education, not by advocating thrift and temperance, not by urging the workman to improve his mechanical dexterity, the thoroughness of his work and the amount which he produces, but by holding out visions of shortened hours of labour, by compelling a minimum of pay which will enable him to live in comfort, of systematically restricting the amount of work done by each individual, even in the shortened day, all under the fatal illusion that by such means a greater number of men will find more remunerative employment.

The employer is usually credited by the trade leaders with accumulating wealth without effort, risk, or anxiety by the slavish labour of his operatives, while the proofs to the contrary, so easily to be obtained in the slender dividends declared by most industrial enterprises and in the records of the Bankruptcy Courts, are steadily kept out of view.

There would be no fault to find with the new class of professional agitators, who live by the discontent which they foment, were they, and the Unions which they manipulate, to contribute in the smallest degree to the obtaining of that work and of those orders in the execution of which the wage-earning portion of the community have their being. This, the most difficult part of every commercial enterprise, is left to the much-abused capitalist, so that the absurd and impossible system is fast asserting itself, that professional skill, mercantile ability and capital shall obtain the work and run all the risks of design, execution and financial security; but that work shall be carried out according to rules which self-constituted and perfectly irresponsible bodies choose to impose. The smallest acquaintance wfth the principles of political economy would demonstrate that such methods must end in ruin; that they are utterly incompatible with our policy of Free Trade—a system which is perfectly reasonable and proper thoroughly carried out, and which certainly never contemplated the protection of one particular class, and that, not by edict of the State but at the bidding of self-constituted tribunals whose claims amount to this:—that there shall be free trade in all products which the operatives require to buy, but the strictest protection as to all that they have to sell, namely their labour, and whose ultimate methods are violence and the coercion of all who differ from views which many intelligent but timid workmen know to be at variance with the true interests of their class.

Under all this lies the socialistic idea of equality in the condition of every member of the commuity, an idea which Political Economy demonstrates to be utterly Utopian and impossible. Since the creation of mankind, the differences in social position and in material comfort which follow naturally from the endless variations of mental and bodily powers in men have existed, and in spite of many abortive attempts, more or less violent, to establish equality, will exist for ever.

However much we may regret the inequality which exists in the distribution of wealth and comfort, it is just as much a law of

* Abstract of the "James Forrest" Lecture, delivered before the Institution of Civil Engineers, May 4, 1893.

Digitized by Google

Nature as the unequal distribution of warmth, of sunshine, or of rain, and seems to me to follow naturally and inevitably from the endless variations in the physical, moral, and mental powers of human beings, and, therefore, to be as unalterable at the bidding of man as these attributes are. It only remains for us to recognise the fact, to make the best of it, and to avoid the gross wickedness of attempting to delude the poorer and more ignorant members of the community by incessant representations that it is the greed and selfishness of the wealthy which keep them low.

If the so-called "working man" be the embodiment of all that is needed for the industrial prosperity of a country, and if the possession of capital and the far wider consequence, the existence of credit, be a crime, why does he not arise in his strength and exhibit the faculties of combination which are so well illustrated in the trades unions, and establish engineering works and manufactories, or undertake engineering enterprises from which he will be able himself to reap the golden harvest which the capitalist and the shareholder are supposed to gather, and who thereby excite his envy and arouse his hatred? The reason is very obvious.

Saturday night comes with unfailing regularity, and the week's wages must be met; work has to be found, usually at prices to be calculated beforehand, and when obtained, contracts do not always go on smoothly; engines and machines will not always work; accidents will happen; long credits must be given; and those men who possess the talent and education to originate and the skill to administer are comparatively very few, even in this land of enterprise, and have their value which it is too much to expect that they will not take advantage of; while the buildings, machinery, stock and floating money which form the capital—of the true nature of which such terrible ignorance exists—are absolutely valueless without the skill and the industry necessary to obtain remunerative employment; while the matter of credit, on which so large an amount of our activity depends, is almost a personal matter, and could never be commanded by a body of operatives, however respectable.

In deference, I presume, to the immense numerical importance of the operative classes, politicians are vieing with each other in supporting the impossible claims put forth—claims which, if conceded, will only precipitate the ruin of the class they profess to benefit, and which already, in the form of what may be termed benevolent legislation in favour of the operative, is heaping up elements of cost which our productive energy is unable to bear. The absurd cry that manual labour is the sole source of wealth has been well combated by that acute reasoner, Mr. Macfarlane Gray, who, in a recent discussion on the labour question, happily compared the body politic to a tree. The popular belief is that plants are nourished through their roots, which for that reason are believed to be the all-important parts, while the leaves are mere ornaments, enjoying the upper air and sunshine and profiting by the work done underground. But a juster knowledge, one of the fruits of abstract investigation, tells us that the roots are mainly useful in holding the tree erect, and have comparatively little to do with providing the materials for building up its structure. It is the leaves which form the great laboratory in which the main components of the plant are extracted from the region where superficial observers would least expect to find them—namely, from the atmosphere. He compares the roots to the operatives' part of the community; the trunk and leaves to the monetary, the scientific and the commercial part which drew from far and wide that which is necessary to keep the growth advancing and maintain it in health. The roots may just as well claim to be the sole sources of life in the tree as the operatives may claim to be the only producers of wealth; and, conversely, the leaves could, with as much reason, consider themselves as the only essential portion of the plant as the merchant or the capitalist claim to be independent of the operatives. Each grade in the body politic is essential to the other; it is an axiom that there can be no degrees of comparison between essential parts; and those who, from ignorance or from interested motives, persistently preach the doctrine of the superior importance of the "masses" over the "classes" are inflicting a deep injury on the prosperity of the country, and especially on those whom they so grossly flatter.

It seems to me that a very great national danger is being incurred by this systematic neglect of Political Economy—an abstract science which had its origin in this country, but where its teachings are ignored in a manner which must end in disaster, the signs of the advent of which are, I fear, only too plainly apparent.

Even in my lifetime a great change has come over the methods of executing engineering work. During my apprenticeship in Manchester I was associated with workmen—millwrights they were called—perfectly uneducated, but of the utmost intelligence—men whose workboxes contained the tools of nearly every trade, and who could handle those tools with dexterity and skill. Before the days of easy communication they were sent away to great distances in charge of works, both extensive and intricate, and executed them, as a rule, with a thoroughness and an intelligence which left nothing to desire. The necessities of the present age have rendered great subdivision of work inevitable, so that there are but few mechanics left who are conversant with many trades, or whose characters and experience enable them to be as self-contained and trustworthy as the millwright of old; hence it seems to me hopeless to expect that, in the engineering trades at any rate, the workmen will ever be able to dispense with the commercially-educated and experienced capitalist and the highly-trained scientific staff he finds it necessary to employ.

And let it not be supposed that this, and kindred institutions, have no interest in the question. Our prosperity rests upon the well-being of our members, and that again depends upon the activity of trade and upon the existence of enterprise. But the "dividend-grabbers," as investors in industrial enterprises are elegantly called by the foolish and ignorant men by whom the operatives are content to be led, will not embark their money in ventures where there is no prospect of reasonable interest, or where the hopes of such interest are endangered by labour agitations, encouraged, to a great and fatal extent, by political parties, who do not scruple to purchase votes by holding out all kinds of Utopian prospects.

But money must be invested; it cannot, in these days, be hoarded in strong boxes, as it was in Pepys's time; consequently our capitalists will search for outlets abroad, and, by promoting industrial undertakings outside our shores, will, through the action of free trade, beat down the value of produce still more, and so further arrest the development of that manufacturing and engineering enterprise upon which prosperity depends.

One method of combating this, I have pointed out, is the dissemination of sounder views on Political Economy concurrently with the spread of technical education. The other course is to pay more attention to abstract science and to devote more time to the study of what is going on around us in the world. I am afraid that the nature of the education of the wealthier classes in this country is responsible for a good deal of the insular conceit and exclusiveness with which, in spite of our peripatetic tendencies, we are still afflicted. Classical education, no doubt, has its merits, and is well suited to a large section of the community; but in these days of the extensive scientific knowledge which a competent engineer is bound to acquire, the universal application of the method seems to be a mistake, while I cannot but think that the acquisition of modern languages and scientific study are fully as efficient in training the minds of the young as they are incomparably more useful in the battle of life afterwards.

Nor am I singular in this view. Successive Presidents of this Institution, in their inaugural addresses, have dwelt upon the cardinal importance of the education question, and within the last two or three years the Council has exacted conditions as to liberal education and scientific training from the candidates for student membership, which cannot be regarded as otherwise than happy; and without doubt, before very long, even in the higher grades of membership, evidence will be demanded of special attainments in abstract science which are now so accessible to all in every part of the kingdom. I do not for a moment lose sight of the practical training, which I consider so essential to the qualifications of an accomplished engineer. I recognise the fact that there is a tendency in the pendulum of knowledge to swing to the opposite extreme, and of the rising generation of engineers to wax conceited and to imagine that the diplomas obtained at Universities are guarantees of fitness to commence professional work at once. And here, again, I am in accord with many Past-Presidents, who, in their addresses, have dwelt on the importance of practical training. I hold that the engineer's education should begin earlier, even at school, and should embrace those branches of knowledge which in our great public schools are still in a great measure ignored or taught in a half-hearted manner, more as a concession to the utilitarian spirit of the age than as an essential equipment for many professions.

But nothing, save bitter experience, will alter the course of events. It seems to be the fate of peoples to attack social problems from the wrong end, to solve them by the painful and dilatory process of trial and error, rather than by means of investigation based on first principles. And this method is commonly applied to engineering problems also. Random trials, as a rule, are the methods by which great results have been achieved, while the application of the scientific principles involved have been left to other heads long after the results sought have been attained at much needless cost, and by much unnecessary expenditure of labour and of time.

(To be continued.)

A Projected Very Long-Distance Telephone Line.—The Automatic Telephone Company of Canada, which has just been incorporated, proposes, it is said, to run a telephone trunk line from Halifax to Vancouver, a distance of 3,500 miles.

THEORY AND PRACTICE.

The following extract from Sir Benjamin Baker's remarks in the discussion on Graving Docks at the Institution of Civil Engineers, deserves the fullest publicity :—

"Bearing upon the general question of the value of theoretical investigations of strength, in cases such as a flat concrete invert, as compared with direct practical experience, he might say that several cases recently had made him a little nervous as to whether the results of the high technical training of the present day with many young engineers did not lead to a dangerous confidence in theoretical deductions and the use of formulas. No one could charge him with contempt of theory ; but cases had been brought under his notice rather frequently of late showing too great confidence on the part of young engineers in theoretical deductions, in preference to going to the same extent as their predecessors had been in the habit of doing to previous examples, in order to see what was the right proportion to adopt in a particular work. Only a few days ago a young engineer at a judicial inquiry attacked the stability of a work, not because it had shown any sign of failure or weakness, but simply because the theory from which he calculated its strength led him to think that the work should have failed. He did not seem to see that if his theory was at variance with practical observation he ought to revise his theory, and make it fit in with the facts. On the theory advanced, the work must have failed unless the tensile strength of green brickwork in mortar was such that a rope could be constructed of that material which would carry its own weight hanging vertically for a height of 220 feet. That consequence did not strike the young theoretician as at all absurd. Another case was one from the Antipodes, and that was really so good that he would like to read out of a Blue Book containing a report of the proceedings of a Royal Commission one or two questions and answers in illustration of the point he was referring to. 'Q. How long have you been an Associate Member of the Institution of Civil Engineers ? A. About two years. Would you like to know why it is such a short time ? Q. I did not ask you. A. Well, I would like to qualify the answer. The reason I did not become an Associate Member before was that when I contemplated coming to Australia I was certainly not aware that they thought so much of the fact that a man was a member of the Institution ; but when I arrived here I found, to my surprise, that they thought more of that Institution, in which the greatest number of duffers that I know in the profession are congregated, than of the University degree of Master of Engineering, which I hold, one of the highest in the United Kingdom. Learning that such was the case I became a member, as I say, two years ago. As a matter of fact, I could have been a member at least ten years previously. Q. But you are not a member now ? A. I am a corporate member now.' That gentleman was labouring under the delusion that the degree of 'Master of Engineering' in some strange way constituted a man an engineer. He proceeded in his evidence to talk about the admissible weight on the driving-wheels of locomotives for given weights of rails, and adduced calculations that were pitiful to contemplate. Sir Benjamin Baker never read anything more ridiculous in its way in his life. This 'Master of Engineering' found no difficulty in calculating the stress per square inch upon a rail under traffic to the hundredth of a ton, and in condemning a certain rail as too light. He had not enough practical knowledge, however, to see that the critical time in the life of a rail was not when it was new, but when it had lost, perhaps, 20 per cent. of its weight by wear and rust ; and he had only to apply his theory to a worn rail on the London and North-Western Railway, or any other important line in the world, to find that the stresses which he considered should not be exceeded were universally exceeded as a matter of daily practice with perfect safety ; and so his theoretical criticism went for nought. A case like this should serve as a warning to students against imagining that if they had taken a degree in engineering, or had left a University with the highest credentials, they were, therefore, necessarily engineers. No doubt they had been supplied with an invaluable box of tools, but if those tools were not properly used they might cut their own fingers very badly and also injure their employers. Theoretical knowledge was no substitute for the practical experience upon which their predecessors in this Institution had chiefly relied. This was not only necessary in works of the kind they were discussing, which really were very complicated as dealing with concrete and masonry, but also when apparently simple problems concerned with iron or steel were under consideration. For example, to take a very simple case, who was there among their students who would not be perfectly prepared to tell them what was the maximum stress per square inch on a tube of given diameter and thickness subjected to internal pressure of a certain amount within the elastic limit ? They would work out the answer to any number of places of decimals. Say that it was 7·55 tons per square inch. If the question was put to all the senior wranglers in the kingdom, they also would say unanimously 7·55 tons ; but if put to three poor mechanics, like the Director-General of Ordnance Factories (Dr. William Anderson), Sir Frederick Bramwell, and himself, they would say, 'We do not know.' It might be 7·55 tons, it might be 12·55 tons ; they could not tell nor even approximate to it unless they knew certain facts about the treatment of the steel which only practical men would consider of importance. That was a simple instance of the absolute necessity in practice of viewing with great suspicion theoretical deductions, which, from the great trouble involved in performing the calculations, often led one to attach too great value to the results."

AN ELECTRICAL PUMPING PLANT.

An electrical pumping plant has recently been designed and fixed by Messrs. Easton and Anderson at the brewery of Messrs. Warwicks and Richardsons, Newark-on-Trent. A source of water suitable for brewery purposes was found by sinking a well in a field about a mile and an-eighth from the brewery.

Messrs. Easton and Anderson undertook to supply plant for pumping this water by a motor to a tank on the top of the brewery. The question at once arose : Should the conductors be overhead or underground ? It was manifestly better that they should be underground, as it avoided the use of unsightly poles and wires, which would be more liable to injury, though, of course, more accessible for repairs ; the cost of underground cables suitable for the purpose appeared at first sight, however, to put them altogether out of court.

There was, however, one circumstance in which this work differed from the ordinary electric transmission plant, and that was that a water-pipe had to be laid to the brewery from the well, and this involved getting cut a trench. It occurred to Messrs. Easton and Anderson that if a pair of cables could be laid in the trench at the same time as the pipe the cost would be very materially reduced, and, on going into the matter, it was found that while the plan would not be cheaper than posts and naked overhead conductors, it was not very much dearer ; so that it was eventually decided to use the underground system. It was thought at one time that the pipe main might have been used for a return instead of a second cable, but the idea was not acted upon. It was considered desirable to be able to automatically vary the speed of the motor by varying that of the engine, and this condition was easily fulfilled by making the dynamo and motor both series-wound.

The plant is as follows :—The dynamo is of the "Whitehall" type, having slotted armature and double magnetic circuit, the field-magnets being of cast iron. It is, as before stated, series-wound for 360 volts and about 15 amperes at 900 revolutions. It stands on sliding rails, and is driven by a link belt from a countershaft which derives its motion by a belt from a horizontal single-cylinder non-condensing engine, which with the countershaft was already in existence. At present this engine does very little other work, but as it is too large for the pumping, it is contemplated to use it for other purposes, and therefore the pulley on the countershaft which drives the dynamo is fitted with a friction clutch, which enables the dynamo to be readily started or stopped as required, independently of the engine.

Suitable fuses and cut-outs are provided in the engine house, and from them the cable is led to the pumps. An ammeter is also fixed here, so that the engine driver can see that the current is being properly supplied. The cable was made by Messrs. Callender and Co., and is of their armoured type, so that it cannot easily be injured as it lies in the ground. The conductor consists of seven wires, each 0·054in. diameter, giving a total sectional area of 0·0155 square inches, and a maximum resistance of 2·84 ohms per mile, insulated by means of a solid sheet of vulcanised bitumen, taped and secured with jute yarn, armoured by means of 20 galvanised iron wires, and finished by a braiding of hemp yarn well compounded. It is laid in a special trench for a short distance till it joins the delivery pipe main leading to the tank, and from thence the two go together to the pump house, at a depth of about 2ft. below the surface of the ground.

There are only two joints on each of the two cables, and as the workmen laid the pipe they laid the cables, one on each side in the trench, leaving the part to be jointed open till the work was done, when a special man was sent by Messrs. Callender, who made the joints and tested the line. The pipe main consists of 5in. cast-iron socket and spigot pipe, for the most part jointed in the ordinary way. At one point the pipes have to cross a railway bridge over a canal, and here—in order to occupy as little space as possible—they are of wrought iron with flange joints, and are made only 4in. diameter, carefully enclosed and lagged to keep them from the effects of frost, the cables also being included in the same casing to preserve them from injury. The ground is low and wet, and the pipes and cable in some places pass under ditches, and were then actually laid below the water level.

The pump house is situated a few yards from the well. The outlet from the rising main at the tank is 70 to 80ft. above the

Digitized by Google

surface of the water in the well. The pumps are of the ordinary three-throw type of Messrs. Easton and Anderson's standard pattern, with gun-metal valves. The barrels are 5½in. diameter and 12in. stroke. The pump crankshaft is driven from a countershaft by means of a cast iron pinion and wheel; and the motor in its turn drives the countershaft through the medium of a gun-metal pinion and a mortice wheel, the teeth of which are accurately machined to a special shape.

The motor is fixed on a concrete foundation, in such a way that it is readily accessible on all sides, which is a very desirable thing where space permits. It is of the same type as the dynamo, and is likewise series wound, to run with 260 volts at a speed of 600 revolutions, at which the pumps will make 28 revolutions per minute, and are calculated to deliver 5,000 gallons per hour to the brewery. The bearings of the motor are made self-oiling, by having each brass bush made in two lengths with a gap between them in which an endless pitch chain of brass rests on the spindle and dips into an oil well beneath the bearing. When the spindle rotates, it carries the chain round and brings up a supply of oil which is deposited on the spindle and finds its way along the bearings by means of grooves, eventually returning from the outer ends of the bearings to the oil receptacle. Thus the motor may run for weeks or even months without any attention to the lubrication being necessary. The lubricators on the pump are of the ordinary needle type, which last a considerable time without attention. For stopping and starting the motor at the pump house a suitable switch and resistance frame is provided.

A NEW FORM OF PORTABLE PHOTOMETER.*

BY SIR DAVID SALOMONS.

If two nicol prisms be mounted in a tube and a source of light is observed through them, then the amount of light which will reach the eye is governed by a well-known law depending on the relative positions of the prisms to one another. The quantity of light passing depends upon a function of the angle which the polarising plane of the polarising prism makes with the polarising plane of the analyser. And since one half of the light issuing from the source of illumination observed will never reach the eye (*i.e.*, the ordinary ray which is thrown out by the polariser), the light which reaches the eye will be half the original light multiplied by a function of the angle included between the polarising planes of the two nicols. This function is the square of the cosine of the angle included between the two planes mentioned. Consequently, the quantity of light reaching the eye from a given source will be governed by the well-known formula, as follows:—

Let I = intensity of the light observed,
,, L = light which reaches the eye,
,, O = ordinary ray in polariser,
,, E = extraordinary ray in polariser,
,, θ = angle between the planes of polarisation of polariser and analyser,

the light which reaches the analyser is E, or I/2, since O = E and I = O + E.

The amount of light which reaches the eye is expressed by the equation,

$$L = \cos^2\theta\, E \text{ or } L = \tfrac{1}{2}\cos^2\theta\, I;$$

hence L varies as $\cos^2\theta$.

In this instrument two tubes are mounted as a binocular capable of being adjusted for distance apart, in order to suit the eyes of different individuals, and the hinge portion used for such adjustment is made without a stop, so that the position of the tubes may be reversed in its relation to the eyes. Each of these tubes contains two nicols arranged as usual; but, instead of the analyser being revolved, the polariser is capable of being turned. The polarising plane of the analyser is set at 45deg. from the vertical in order to obtain the scales in a convenient position upon the tubes.

Consider for a moment one of the tubes—a description of which applies to the second. The polariser is so mounted that its position is indicated upon two scales at the same time, the one being graduated in degrees to be used for accurate work and the other graduated in divisions indicating what proportion of the light observed will reach the eye. One scale is called the "degree scale," and the other the "light proportion scale." The latter scale is so graduated that it reads unity for the "light field," and zero for the "dark field." The intermediate division numbers are 0·1, 0·2, and so on. This scale is used for approximate measurement.

When the "light proportion scale" reads unity the "degree scale" indicates 0deg., and when the former shows zero the latter scale reads 90deg.

* Paper read before the Institution of Electrical Engineers, March 23rd last.

The method of determining the positions of the divisions:—

We have $L = \tfrac{1}{2}\cos^2\theta\, I = \cos^2\theta\, \frac{I}{2}$.

Now equate ..... $\text{Cos}^2\theta = 0{\cdot}1$,

$\text{Cos}^2\theta = 0{\cdot}2$,

and so on.

Solve each equation, and the values of the angles so found are the successive points on the scale required. The following table gives the angles by working to three decimal places in making the calculation:—

Divisions upon the "light proportion scale."	θ.	
0	90°	no light passes.
0·1	71° 26′	
0·2	63° 34′	
0·3	56° 13′	
0·4	50° 14′	
0·5	45°	
0·6	39° 46′	
0·7	33° 47′	
0·8	26° 26′	
0·9	18° 34′	
1·0	0°	maximum light passes.

If the values for $\cos^2\theta$ for the right hand and left hand tubes are A and A′, and the values of the lights observed with the right and left tubes are I and I′.

Since the photometer is balanced at the start, each eye receives the same amount of light; it is therefore correct to equate $L = A\frac{I}{2}$ and $L = A'\frac{I'}{2}$. It is evident the result will remain unaltered if we regard these equations as L = A I and L = A′ I′, and it will save the observer the trouble of doubling the final result.

In front of the polariser a small round opal, or some equivalent, screen is placed; and the light upon this screen is that which is directly to be observed. The screen is mounted in a cell and on the end of the tube. A lens is inserted in the tube to focus this screen upon the retina. This screen may be removed. When desired, an adjustable lens may be added in front of the observation tube to focus the light in the plane of the screen. In some cases this may be convenient.

To make an observation with this instrument it is placed before the eyes in the same way as a field glass, each polariser having been turned to the position of "light field," when the "degree scale" will indicate zero degrees, and the "light proportion scale" will read 1. One tube is now directed towards the source of light under examination, and the other tube towards some known standard radiant. The distance of the light under observation, and the distance of the radiant from their respective screens (which are before the polarisers) are measured. Then, according to the usual methods of photometric measurement, assuming that the source of light under observation cannot be moved, it would be necessary to shift the standard radiant in order to get a balance—*i.e.*, to render the screen, observed by each eye, illuminated at the same intensity. Instead of shifting the standard radiant, the balance with this instrument is obtained by revolving the polariser which faces the brighter screen (should any difference exist) in order to reduce the illumination of both screens to the same apparent intensity. The value of the light under investigation in terms of the standard may be calculated when the amount of light cut off by the polariser, the distances of the two sources of illumination in question, and the value of the standard illuminant, are known.

It should be again observed that, since the ordinary ray reaches neither eye, it is equivalent to an equation each side of which is divided by 2; and, consequently, the final result will be the same as if no such division by 2 existed.

To make such an instrument thoroughly practical several mechanical appliances are necessary, and exist in this instrument. It will be a convenience if the standard radiant can be placed always at such a distance that the square of this distance shall be unity; and instead of this radiant being in front of the instrument—which would cause it to shed light on the other screen, or be in the way—it should be placed at the side, and illuminate its screen by means of a right-angled reflecting prism, and the arrangement is such in this apparatus.

The comparison radiant for this instrument consists of a standard candle contained in a tube, the candle being fed up by means of a spring, the top of the tube forming an abutment to keep the candle flame at one level, although the length of the candle is always altering. This abutment piece is surrounded by a cup to catch any grease which may run over. The candle tube has a slot cut in it in order that the amount of candle in the tube may be observed at any moment. The candle tube is carried in a light framework, which supports a metal cylinder that acts as a chimney to keep off draughts. This chimney has in it a small window into which slides a slip of clear glass, and it is through this window that the light

Digitized by Google

from the candle passes to illuminate its screen. The clear glass may be replaced by tinted glass when desired.

The chimney is carried in a special form of gimbals, so that, no matter what inclination may be given to the binocular, the candle will always remain vertical, since the gimbals are attached to the binocular by means of an arm. The inner ring of the gimbals is in reality only half a ring, and the plane of the outer ring when the candle is vertical, instead of being at right angles to the axis of the candle, is oblique to its axis. This construction is necessary, otherwise the rings would come before the window in the chimney and so obstruct the light. In front of this window is placed a suitably-shaped tube capable of being lengthened and shortened, if required, and which fills up the space between this window and the reflecting prism, this prism being situated in front of the screen at the end of the tube containing the nicols. The object to be secured is that extraneous light should be kept from this screen. The weight of this adjusting tube is counterpoised so that the candle may always remain vertical. The arm connecting the candle with all its supplementary apparatus is carried upon its observation tube (which contains the nicols) by means of a ring arranged in such a way that, although removable, it cannot turn except to a small degree by means of an automatic motion. The reflecting prism also is carried in a similar way. The arm has two motions upon it—one a clamping joint to enable the candle flame to be brought in front of the prism to a nicety and the other a kind of parallel motion arrangement by which the candle can be placed to two given distances from the prism, according as the parallel arrangement (somewhat similar to a parallel ruler) is pushed to the one side or to the other. The measurements and the arrangements of the details are all so adjusted that the candle flame will always be facing the reflecting prism for all inclinations of the binocular, and the two distances to which the candle may be moved are so regulated that the apparent distances of the flame from the screen it illuminates shall be either the square-root of 10 or the square-root of 12. These two distances are the most convenient, one for use when measuring by a decimal system, and the other when measurements are made in feet.

It may be mentioned that the candle arrangement with its arm can be removed at pleasure, so also can the reflecting prism. It will be noticed that the weight of the candle with its apparatus tends to twist the ring round upon the tube containing the nicols, and it might appear that this could be avoided by simply cutting a slot in the ring to push over a pin screwed into the nicol-tube. This, however, is not feasible; for, in order always to have the relative positions of all parts as they should be, it is essential that the ring which carries the candle and its arm should have a slight circular motion. This is obtained by placing upon the direct observation nicol-tube another ring, which is connected with the candle-arm ring by means of a slotted sliding bar in such a way that the candle apparatus cannot be displaced and the relative positions are always correctly maintained.

A description of this part, simple as it is, would be complex, so that references must be made to the plates attached hereto, by the inspection of which the arrangement will appear clear. The eyes of any one person differ, so that an observation error is sure to be introduced. In order to eliminate this error, the instrument is so arranged that the relative positions of the parts of the instrument can be reversed when a second observation is taken, which is equivalent to an observation with the eyes reversed. A mean of the two observations is then taken. The instrument described has this particular advantage not possessed by other photometers.

At starting it is only necessary to place the candle in its fittings on any of the photometers in general use, in order to ascertain the standard value of the light which issues from the window and from the tube when the latter is used. These two values, which may practically be considered as constants, can be engraved upon the chimney. The loss of light due to the reflecting prism may be ascertained at the same time.

When it is desired to put the instrument (set up and the candle alight) upon a table, it is placed upon a small slender tripod. This tripod, which can be closed to render it portable, accompanies the instrument. It may often be found convenient, when using this apparatus, to place it upon a tripod after the same manner as a theodolite.

This photometer packs up into a sling case barely larger than those used for field glasses.

Some of the advantages derived from this instrument may be stated as follows:—Very powerful arc lights may easily be compared with one another or with a standard source of light. It may be used for measuring various sources of light, such as daylight out of doors with light in a room, and for the estimating of photographic exposures. That the instrument is exceedingly convenient, compact, portable, and easy to use, need scarcely be stated. It may also be employed for rapidly comparing the light in one or more places far apart, which is frequently a great convenience.

Two points alone might be urged against the principle. The first is that nicol prisms are not, as a rule, sufficiently accurate for very close measurements. However, to make these prisms quite accurate, or at any rate sufficiently so for this purpose, is no difficult matter, as may easily be proved by taking a number of nicol prisms at random and testing them. Secondly, errors are introduced due to internal reflections as well as reflections which take place at the surfaces of the prisms. These losses occur for the nicols in both tubes, and when the losses in each tube are deducted from one another for any positions of the nicols, the difference will be found to be so small as to affect to an inappreciable extent the result.

The nicol prisms in the tubes might be dispensed with and be replaced by adjustable diaphragms somewhat similar to the "Iris" pattern, one being placed in each tube, and an index scale showing the area which is free for the light to pass, as well as a proportion scale for reading the quantity of light which passes without calculation. The principle, of course, would remain the same as that already described.

Again, it might be possible to vary the proportion of light passing down the tubes by wedges of tinted glass; but, on the whole, the nicols appear to present so many advantages that a preference was given to their use.

Appended hereto are the formulæ applicable to this apparatus for general work, and it will be unnecessary to refer to any tables or to make tedious calculations excepting in those cases where great accuracy is required, in which event the scale of degrees must be used and the values of the cosines be looked out and squared.

Let X = the light under examination,
" l = the comparison light expressed in standard candles,
" D = the distance in inches of X from the screen of the photometer facing X,
" d = the distance in inches of l from the screen of the photometer facing l,
" θ = the angle between the polarising planes of the nicols in the tube facing X,
" θ' = the angle between the polarising planes of the nicols in the tube facing l;

Then $$\text{Cos}^2\,\theta\,\frac{X}{D^2}=\cos^2\theta'\,\frac{l}{d^2},$$

and $$X=\frac{\cos^2\theta'\,D^2}{\cos^2\theta\,d^2}\,l.$$

Let $$\text{Cos}^2\,\theta=A \text{ and } \cos^2\theta'=A',$$

then $$X=\frac{A'}{A}\,\frac{D^2}{d^2}\,l.$$

In this photometer d may be made $\sqrt{10}$ or $\sqrt{12}$, so that the last equation may be written,

$$X=\frac{A'}{A}\cdot\frac{D^2}{10}\,l \text{ or } \frac{A'}{A}\cdot\frac{D^2}{12}\,l,$$

according to the value of d.

If D is divided by 12 the distance will be expressed in feet.

Let $$\frac{D}{12}=D'$$

then $$X=\frac{A'}{A}\cdot\frac{D^2}{12}\,l \quad \ldots\ldots\ldots (1)$$

when distances are given in inches,

and $$X=\frac{A'\,D'^2\,l}{A} \quad \ldots\ldots\ldots (2)$$

when distances are expressed in feet.

When the values of A and A' are calculated from the "degree scale," certain special cases occur which simplify the equations. They are when $\theta=0$ deg., $\theta'=0$ deg., $\theta=\theta'=0$ deg., $\theta=45$ deg., and when $\theta'=45$ deg. In these cases A and A' will become unity for 0 deg. and $\frac{1}{2}$ for 45 deg.

With most observations the value of A' will be 1, and equations (1) and (2) will then become

$$X=\frac{D^2\,l}{10\,A'}, \quad \ldots\ldots\ldots (3)$$

and $$X=\frac{D'^2\,l}{A}. \quad \ldots\ldots\ldots (4)$$

When the values of A and A' are obtained from the "light proportion scale," the values are in decimals of one place, so that these figures may be read as whole numbers multiplied by 0·1.

Equations (3) and (4) may then be written

$$X=\frac{D^2\,l}{10\,A\times 0{\cdot}1}=\frac{D^2\,l}{A}, \quad \ldots\ldots (5)$$

and $$X=\frac{D'^2\,l}{A\times 0{\cdot}1}=\frac{10\,D'^2\,l}{A}. \quad \ldots\ldots (6)$$

Putting these equations into words :—

Rule 1.—When only the light under observation is reduced by turning the polariser, the "light proportion scale" is used, and the distance of this light from the screen is given in inches, then the square of this distance multiplied by the standard comparison

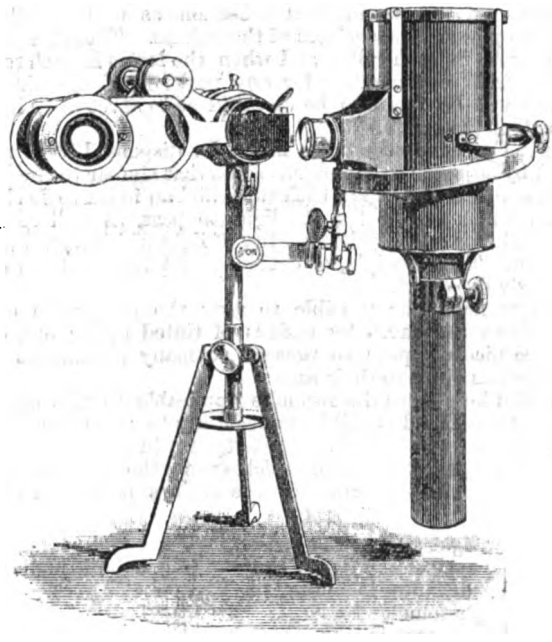

FIG. 1.

light in candles and this product divided by the reading on the "light proportion scale" (read as a whole number) gives the value in standard candles of the light observed.

Rule 2.—When only the light under observation is reduced by turning the polariser, the "light proportion scale" is used, and the distance of this light from the screen is given in feet, then the square of this distance multiplied by 10 and by the standard comparison light in candles and the products divided by the reading on the "light proportion scale" (read as a whole number) gives the value in standard candles of the light observed.

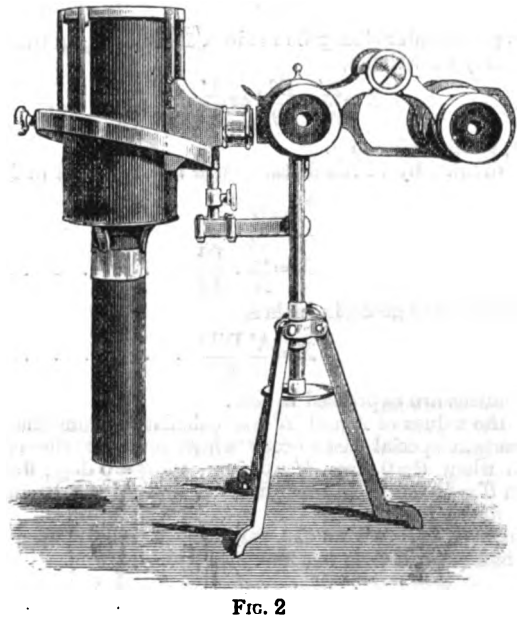

FIG. 2

Fig. 1 shows the instrument set up for use upon the tripod. On the right is shown the candle-tube, with chimney and screening tube, set in its gimbals, the whole supported by the arm which connects it with one tube of the binocular. The tube of the binocular nearest the candle has the reflecting prism upon it. The end of the other tube shows the opal screen. The long link embracing this tube and connected with the other one is the portion which gives the automatic adjustment to the reflecting prism and candle arm. The distancing arrangement for the candle is seen at right-hand end of the candle-arm.

When the photometer is used it is lifted off the tripod.

Fig. 2 is the reverse view of the last one, and shows the appearance of the instrument as seen from the side which faces the eyes.

Fig. 3 shows the arrangement of the binocular portion of the photometer diagramatically. At the top is shown the scale of divisions of the "light proportion scale." In the centre the end view of binocular is illustrated, showing on one tube a screen, and on the other tube the reflecting prism covering its screen.

The lower diagram is a side view. On the left tube is seen one scale, the second one is on the other side. The centre portion

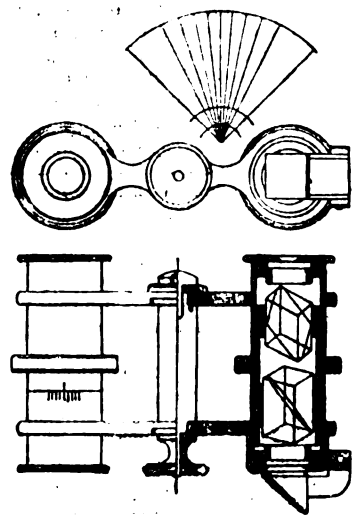

FIG. 3

is the hinge with a clamping nut, and the right tube is shown in section, with the reflecting prism attached.

DISCUSSION.

Mr. ROBINSON asked whether the standard of light could be taken at once ; for instance, in comparison with the unit of light could any test be made directly of the light?

Sir DAVID SALOMONS : Yes.

*Prof. CROOKES said they were greatly indebted to Sir David for bringing before them so very compact, portable, and beautiful a form of photometer ; but there was one weak link in the chain, and a chain was only as strong as its weakest link. Sir David used a candle as a standard. Now, a candle was the most imperfect standard that one could have. No two standard candles agreed. He thought he was under the mark in saying that there were variations of 10 per cent. between one set of standard candles and another. He knew that candles were very largely used for photometric purposes, but they were admitted to be so imperfect that he thought electrical engineers ought to devise something better and more trustworthy, and he did not think that the difficulties were at all too great to be got over if attention was devoted to the subject.

*Mr. TROTTER said that he felt hardly competent to offer any remarks upon the Paper, as he had not had the pleasure of reading it, and could not quite comprehend the instrument from the short description of it which they had just heard ; still less could he criticise such an instrument until he had worked with it. There was always a difficulty in eye-piece instruments. He remembered Captain Abney calling attention some time ago to the great advantage in photometric work of looking at the screen from a distance, and with both eyes. One felt a great constraint with eye-piece instruments, and he was quite sure that was one reason why the German so-called subjective method of reading galvanometers was not used much in this country. It seemed that the half-image principle which was so familiar in saccharimeters could be applied to this. Looking through one eye-piece only, they would have the light reflected from the prism through half the telescope, and through the other half they would see the light to be compared with it. A candle was very bad as a standard, but in a photometer they wanted a secondary standard only to carry about to compare with the standard which was kept at home ; in the same way, a foot rule was not the standard, it was only a secondary standard, which was carried about, which one believed had been checked by somebody at one time or another against a real standard. In that way a glow-lamp would be a good secondary standard, because it could be checked before leaving home upon a photometric expedition, and again on coming back. In ordinary photometric work, where a standard candle had to be used, a good many calculations and corrections had to be made in order to get anything like accuracy.

*Prof. AYRTON confessed that he felt some doubt, not having used the instrument, as to the ease with which they could compare two lights when they were looking at one with one eye and at the other with the other eye. The two eyes would give one appearance, and it would be very difficult to know which of the two lights was the brighter. He had found a candle pushed up by a spring through the nozzle to be very uncertain as to its illuminating power. There was another thing which it was very important to be able to do with a photometer when they were comparing lights of very different colours, that was to be able to vary the inten-

Digitized by Google

sity of one of the lights rapidly backwards and forwards, rapidly diminishing the amplitude of the oscillation to a point which they stopped at. He quite agreed, therefore, with Mr. Crookes that the glow-lamp formed a much better standard. There was no necessity, however, to use an ammeter and voltmeter; it was quite sufficient to use an ammeter. If they knew the current through the lamp, then they would be able to get the brightness of the light. He might take this opportunity of mentioning that he had had experiments going on in his optical laboratory for some years past, with running lamps at very much below their normal brilliancy. He did not propose to state now how far they had obtained perfect constancy, but the experiment that they had been trying (and it had been going on now for some years) was to see whether they could or could not say that the light given out by a lamp, when a perfectly definite current was sent through that lamp (which was never raised to anything like like its normal brilliancy, so that, practically, there was no fear of blackening the glass), would for years be a perfectly definite thing. He was in hopes that the result would be "yes," but he was not quite clear about it yet, although it was sometime since they started the investigation. Supposing the answer was yes, then all they had to do was to take a glow-lamp and send through the filament of that glow-lamp a certain definite current which it would be very easy to measure with perfect accuracy by means of a set-up ammeter, that is an ammeter which read between two limits, whatever they might be—the tenth of an ammeter and the fifteenth of an ammeter—a *current gauge* which read one current with extreme accuracy and read no other current at all. He hoped to be able to supply a practical standard of light which would have none of the disadvantages of the standard candle, which would not, of course, be affected by wind, and which would give exactly the same results from one time of the year to another.

*Mr. FAIRFAX said that he had been making some photometric experiments for the last two years upon daylight. Although the north light was supposed to be extremely steady, yet if there were clouds passing across, the light would vary within ten or fifteen seconds. He had been doing that with a very simple arrangement. It was just a silver napkin ring. Mr. Lovibond, who invented the tintometer, told him that the only white light that he could get was that of a sea fog.

Sir DAVID SALOMONS: Will you show us how you use it?

*Mr. FAIRFAX: I simply put it on a white surface. The various rays of light fall as a cardioid curve on a white horizontal surface placed beneath it. The main point to be observed is that either the photometer or the source of light should always be at a certain definite angle, so that in measuring two lights, one at a greater distance than the other, the angle with the ring should always be the same.

*Sir DAVID SALOMONS, in reply, said that the discussion had turned chiefly upon the candle, which was the part that he attached practically no importance to, for the reason that he knew it was extremely imperfect. In order to try and limit the error as far as possible, he had arranged to cut down the light something after the Methven standard method, to make up a little for the deficiencies which would otherwise exist, and to case it with metal fairly close, so that a draught might be started very soon after it was lit. It was tested with a photometer before using; it should be taken at a time when the temperature did not appear to rise beyond the average temperature. The error was not very great, and a candle was one of the most convenient things which could be used at the present moment for carrying about. Incandescent lamps were undoubtedly far better, but they were not convenient things to carry in the pocket together with a secondary battery. Curiously, when Lord Kelvin looked through the instrument the axis of his eye appeared to be somewhat different to that of most people. Lord Kelvin could only see one image like a stereoscopic image. Most people who had looked through it saw two images. The reason why in a binocular, an ordinary field glass, only one image was seen, was the fact that what they were looking at was very far off. In the stereoscope it was necessary to get over the difficulty caused by the fact that the objects were near, and therefore they must have the lenses prismatic in form. They would see two images, not one, unless the axes of the eye were placed a little different to what was usual. No doubt in certain classes of close work, as in watchmakers' work, the axes of the eyes did get somewhat altered from the normal. A Jellett prism would do really what Mr. Trotter suggested, but it was almost impossible to get a perfect Jellett prism cut. It was more a prism of theory than a prism of practice.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *April* 21, 1893.

Electricity at the Chicago Exhibition.—The installation of the exhibits in the electrical building has not proceeded very far up to the present time, but those in charge are confident that the great majority of them will be in proper shape at the opening on May 1st. The floor of the building is covered with packing cases containing exhibits, and these are being taken out as rapidly as possible. The foreign exhibits make a particularly good showing. The immense tower of the General Electric Company is now in process of erection, and when completed will undoubtedly be the most conspicuous object in the building. The Bell Telephone Company is also erecting a building which will attract much attention, and will probably contain a very elaborate exhibit of telephone apparatus. Only one or two of the exhibits are as yet complete. A small army of men are busy, and a few days will undoubtedly see the work nearing completion.

Rapid Transit in New York.—At last the Rapid Transit Commission, after two or three years and the expenditure of some $250,000, has settled upon some definite plan of rapid transit in New York. It may, however, be considered as a temporary relief and as not intended to end the matter or to preclude the possibility of the construction of other lines in the near future. An underground electric railroad was considered by the Commissioners as the ideal method of transportation under the existing conditions, but it will be remembered that when the franchise for the construction of such a road was offered for sale, some months ago, only one bid was received, and that was so ridiculously low that it was not considered. Finding their efforts in this direction blocked, the Commissioners turned their attention to the extension of the present elevated system. An underground road, however, was not lost sight of, and some days ago two propositions were made to the Commission by the banking house of R. D. Wilson and Co., who proposed to organise a company with a capital of $15,000,000, to construct and operate an underground road on condition that the city should loan its credit to the Company to an amount equal to 70 per cent. of the actual cost, the amount, however, not to exceed $35,000,000. Upon investigation it was found that the city could not enter into such an agreement constitutionally, and a second proposition was made to the effect that a company with a capital of $15,000,000 should be formed, and that the city build the road and sell it to this Company at cost; or for the Company to build a small portion of the road and the city to build the rest, which was to be sold to the Company upon its completion. The Mayor of New York, whose veto power in this case is absolute, expressed himself as decidedly opposed to any such arrangement, and the proposition was rejected by the Commission. A few days later the Rapid Transit Commissioners unanimously adopted a plan for the extension of the present Manhattan Elevated Railroad system.

The Columbia Incandescent Lamp Suit.—The case of the Edison Electric Light Company, *et al.* v. Columbia Incandescent Lamp Company, which was tried on April 11th, 12th, 13th, and 14th, excited widespread interest in electrical circles. A very strong case was made, and what has become known as the "Goebel defence" was set up and supplemented by new affidavits, which reached several hundred in number. To-day a decision was handed down by Judge Hallett in favour of the defendant. This decision was in the case of a motion for a preliminary injunction, and two courses are now open to the General Electric Company, first, to press the suit to a final hearing, which would involve the examination of all the witnesses whose affidavits were produced, which would consume probably two years' time, during which the Edison patent probably expire; second, to let the matter drop entirely and allow the few remaining companies which have not been enjoined to continue the manufacture of incandescent lamps. In either case the effect on the lamp industry will be very beneficial.

BOOKS RECEIVED.

"Official Catalogue of the British Section" of the Chicago Exhibition. (London: William Clowes and Sons.) 540 pp., 8vo. Price 25 cents.

"Proceedings of the Royal Society." Vol. LII., No. 320. (London: Harrison and Sons.)

"The Romance of Electricity." By John Munro. (London: Religious Tract Society.) 320 pp., crown 8vo. Price 5s.

"Official Guide to the World's Columbian Exposition, 1893." (London: Reuter's Telegram Company.) European Edition. Price 1s.

"Alternating Currents of Electricity," authorised American edition, by Gisbert Kapp, with an introduction by William Stanley, jun. (New York: W. J. Johnston Company.)

City and Guilds of London Institute: Report to the Governors, 1893. (London: Gresham College.)

"Electricity and Magnetism," by S. R. Bottone. (London: Whittaker and Co.) Crown 8vo.; 200 pp.

CORRESPONDENCE.

GAS POWER FOR ALTERNATING-CURRENT WORKING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In criticising my letter on the above subject in your last week's issue, you seem to have slightly misunderstood me. What I want to point out particularly to gas-engine makers is the importance of "parallel" running in alternating-current systems. You seem to imagine that gas-engine manufacturers are well aware of this, and that my letter was uncalled for. To show you that this is not so, I may mention that, in correspondence which I have had with a leading firm, they admit that they have not taken the trouble to consider the question because they believed *that the use of alternating currents would die out.*

I did not suggest in my letter any alteration of the Otto cycle, but some convenient and cheap arrangement of cylinders to keep up coutinuous impluses. I believe there should be no difficulty in successfully varying the impulses down to half-power.

That the dynamos in a central station should not be arranged to work at light loads does not alter the fact that the chief firms do not make engines capable of driving alternators in parallel *at all*, even at heavy loads.—Yours, &c.,

J. A. MCMULLEN, M.I.E.E.

21, Carlton-hill, St. John's Wood,
London, N.W., May 5, 1893.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

The 1893 Edition of "THE ELECTRICIAN" Electrical Trades Directory and Handbook is NOW READY. This useful book contains over 1,000 pages, and several new and handy features have been added. Price 7s. 6d., post free 8s. 3d.; abroad 8s. 10d. *Comparison with any similar electrical publication is specially invited.*

TENDERS INVITED.—The Ealing Local Board invite tenders for the construction of Lancashire boilers and accessories, which must be in by 12 noon on Wednesday next, the 17th inst.

——— The Urban Sanitary Authority for the Ealing district require tenders for the construction of the necessary machinery and accessories for their electric-lighting scheme. Messrs. Bramwell and Harris, of 5, Great George-street, Westminster, S.W., or Mr. C. Jones, C.E., Surveyor to the Local Board, Ealing, will show the plans any time after Monday the 15th instant, and all specifications and forms of tender can be obtained from either. Tenders must be in by Tuesday, the 30th instant.

——— The tenders invited by the Rochdale Corporation for lighting their Sanitary Works were due yesterday.

——— The Direction-Générale des Postes et des Télégraphes invites tenders for the supply of apparatus for telegraph offices during 1893, in 18 lots. Forms of tender must be obtained before the 14th inst., at the Fourth Bureau of the Division du Matériel et de l'Exploitation Électrique, 153, Rue de Grenelles, Paris, where tenders will be opened on the 24th inst.

TENDERS ACCEPTED.—The Corporation of Dewsbury at their meeting last week provisionally accepted a number of tenders in connection with their electric-lighting scheme, the total amount being £12,000. These tenders will be officially accepted at the next meeting of the Town Council.

——— The Corporation of Cardiff have accepted the tender of Messrs. W. Thomas and Co. for the erection of the first portion of the electric-lighting station at Canton, the amount being £3,328 3s. 2d. This tender was the lowest of four sent in.

——— In *The Electrician* last week, by a misprint Messrs. Simmons and Co. were given as the successful tenderers for the supply of a switchboard to the Aberdeen Corporation. The name should have been Messrs. Siemens, Bros. and Co. (Limited).

APPOINTMENT VACANT.—The Hanley Corporation require an electrical engineer to superintend the construction of the works for the supply of electricity now being carried out for the borough, and to take the management of the works when completed. The salary is to be £200 per annum. Applications must be sent into Mr. Arthur Challinor, Town Clerk, by May 30th.

BANKRUPTCY.—In the case of John Herbert Hale, lately carrying on business at 25, St. Stephen-street, Bristol, as an india-rubber merchant and electrician, the liabilities amount to £722 3s. 5d., and the assets to £405. 5s. 4d.——Austin Herbert, formerly in business as an electrician at Nottingham, but recently adjudicated a bankrupt with liabilities to the amount of £172, and assets £55, has passed his public examination.

DIRECT UNITED STATES CABLE COMPANY (LIMITED).—The Glasgow offices of this Company are now removed to more commodious premises, at 4, Waterloo-street.

THE EDISON AND SWAN COMPANY.—Owing to the large demand upon the City offices of this Company, in Cannon-street, E.C., it has been found necessary to further extend this branch, and additional premises have been taken at 7, Suffolk-lane, E.C., where the office and general business of the City branch will be carried on.

ALLPRESS AND CO.—Mr. Vincent S. Allpress informs us that he has retained the offices of the late firm of Allpress and Belshaw, Victoria-street, Westminster, S.W., where he will carry on business as an electrical engineer and contractor, under the above name.

THE IMPERIAL INSTITUTE.—The electrical apparatus enabling communication with the belfry to start the large peal of bells on the occasion of the opening ceremony was designed and erected by Messrs. Julius Sax and Co. (Limited). The electric lighting of the Queen's lift and the telephonic and bell installation throughout the building was also supplied and erected by this firm. The hydraulic lifts, of which there are several, have been erected by Messrs. Archibald Smith and Stevens.

BOY MESSENGERS.—The business of the Boy Messenger and Electric Call Company (Limited) has been taken over by the District Messenger Service and News Company (Limited).

CEILING ROSES.—We give below an illustration of a new ceiling rose designed by Messrs. King, Mendham and Co. It is made in china and consists of two parts, the plug and its cover, the latter serving as cover and base combined. The plug is divided into four parts by webs and the terminals are fixed through these webs, as shown; an additional terminal is provided to carry the fuse. In wiring, the flexible cord is threaded through holes and knotted before being attached to the proper terminals, and the branch wires are brought through holes in the base of the plug. The wirer is thus able to do his work away from the ceiling, except when he is securing the cover to the block by the three screws. No twisted cord is required, the knot being tied in each single stranded cord, and this relieves the terminals of the weight of the lamp and shade. No thread is used, and as the plug fits loosely into the cover these parts are interchangeable. The makers claim that this rose can be used with high voltages and in any position.

The K.M.B. "Perfect" Ceiling Rose.

THE OERLIKON ALTERNATE-CURRENT MOTOR.—We have received from the above Company their latest list of alternate-current motors, which gives full description, photographic illustrations and details of the machines. These are self-starting and may be switched in, like a direct-current motor, without any series resistance if the machine be started by hand; while the large current at starting does not injure the motor as it would a direct-current one, since there is no commutator or collector. The standard types are from ⅛ to 9 H.P., and vary in speed from 1,800 to 1,150 revolutions per minute, the speed for any individual machine not varying more than 5 per cent. from no load to full load. The efficiency rises from 40 per cent. in the ⅛-H.P. machine to 80 per cent. in the 9-H.P. machines, and the weight from 92lb. to about 10 cwt., and the motors are designed for a frequency of 65 ∿, and a pressure of 110-120 volts. Unfortunately, the most important detail is omitted—the *price* column is left blank. The practice of leaving the prices out of a list is one which is also common in England, and is to be deprecated; it is apt to give customers the idea that the price varies as the customer.

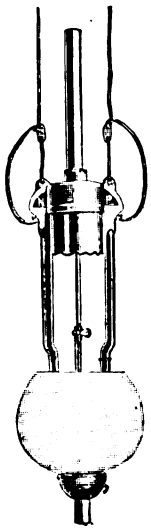
LIVERPOOL OVERHEAD RAILWAY.—We have received from the Electric Construction Corporation an illustrated description of the Liverpool overhead railway and its plant.

ALUMINIUM SOLDERS AND ALLOYS.—Mr. W. A. Briggs, of Dundee, sends us a circular relating to Prof. Richard's solder, and to two alloys, one claiming double the strength of aluminium. The

Digitized by Google

prices being left blank, we are unable to judge of the practical importance of this material. Another alloy is offered for ornamental purposes, in ingots at from 1s. 1d. per lb.

THE WATERHOUSE ARC LAMP.—This is a simple and strongly-made lamp, intended either for series or for parallel running. The feed is a modification of the Brush clamp, but instead of a glycerine dash-pot, a piston is provided on the top of the carbon rod, and works in a brass tube which is screwed to the case. An asbestos cupped washer is fixed on the piston, which while allowing the rod to be moved freely upwards, allows it to descend slowly. Differential magnets and an air dash-pot are used for striking and feeding. The working parts are mounted on a single casting, and a cast-iron



hood, having no screwholes other than for the brass tube already mentioned, protects the lamp from the weather. The upper carbon holder is arranged with a ball and socket as in the Hochhausen lamp. We are informed that only single-carbon lamps are being made at present.

"THE ENGINEERING MAGAZINE."—The May number of this popular American monthly is now ready, price 1s. Vol. V. commenced with the number for April, and the annual subscription to the magazine is 12s. 6d., post free. The contents for May include "Ethics of Architectural Competitions;" "The Gravity System of Rapid Transit;" "Progress in Steam-Engineering," by Prof. R. H. Thurston, Past President Am.Soc.M.E.; "The Cost of Street-Railway Building;" "Prof. Gray's New Telautograph;" by William Maver, Jun.; "The Care of Existing Highways;" and the second part of "English and American Railways," by W. M. Acworth, together with notes on Mechanics, Architecture, Mining and Metallurgy, &c.

"ELECTRICITY THE LIGHT OF TO-DAY."—Under this title Messrs. Sharp and Kent have issued a most attractive book of excellent collotype illustrations of electric-light fittings, with their prices. Interspersed among these are a number of very well executed coloured plates. Though nothing but a catalogue of fittings, Messrs. Sharp and Kent have succeeded in striking out an entirely new line, even where the highest class of printing and pleasing binding has of late been ungrudgingly used. This production may be looked upon as a praiseworthy endeavour to popularise electric lighting, quite as much as an effort to put forward a striking catalogue.

MESSRS. ERNEST SCOTT AND MOUNTAIN (LIMITED).—This firm have secured the contract for lighting the Burnopfield Co-operative Society's extensive premises. The plant will include a 7-H.P. "Priestman" oil engine.

ABERDEEN.—A committee of the Directors of the Northern Co-operative Company have consulted Prof. Kennedy on the subject of lighting their large premises in Loch-street and Gallowgate by electricity. Prof. Kennedy will furnish a report showing the cost of fitting up and working the installation comparatively with that of gas.

BLACKBURN.—Mr. Thomas has been duly elected by the Town Council to serve as electrical engineer during the installation of the electric light in the centre of the town. The appointment is not, we understand, a permanent one.

BOLTON.—Plans for the buildings required for the proposed Central Station have been submitted by Mr. Ryder, the electrical engineer to the Corporation, and have met with the approval of the Gas Committee. Messrs. Hinnell and Murphy have been appointed architects, and the scheme is now to be actively proceeded with.

BRISTOL.—The Electrical Committee of the Corporation will recommend the acceptance of the tender of the Brush Electrical Engineering Company for the supply and erection of transformers, terminal boards, &c., at the various sub-stations, for the sum of £1,752, and the tender of Mr. F. M. Newton for the supply and erection of switchboards, storage batteries, &c., at the central station, for the sum of £1,553. 10s.

BUCKINGHAM.—The charge made by the local Gas Company for lighting the Town Hall clock has averaged between £10 and £11 per annum. Messrs. Parr and Gillies, proprietors of the local Electric Light Company, offered to do the lighting for £5. 6s. per annum; this has brought an offer from the Gas Company to light the clock for £4. 10s.

BURY.—The report of the deputation recently appointed to visit London and several other large towns with a view of studying the electric-lighting question, has been duly presented to the Town Council, and recommends that the Borough Engineer be instructed to prepare conditions upon which a limited number of contractors shall be asked to submit competitive tenders to adopt or recommend such systems of supply and types of motive-power as they must deem best suited to meet the conditions under which the electric lighting for the borough is to be installed. The deputation further recommend that a consulting electrical engineer be appointed to act with the Borough Engineer to advise the Electric Lighting Committee in the preparation of the drawings, estimates, and specifications for the necessary work. The whole of the subject was discussed at the last meeting of the Town Council, and, with slight amendment, the recommendations of the report were adopted.

CITY OF LONDON.—A Court of Common Council has given permission for the City of London Company to carry their mains and tubes over London Bridge. An objection having been taken that the Company had been laying telephone tubes in conjunction with their lighting tubes, Mr. Hudson, on behalf of the Bridge House Estates Committee, assured the Court that the application only related to electric-lighting tubes.

DERRY.—Active preparations in connection with the public electric light installation are reported. The contractors are at work on the generating station at Strand Road, and the number of the standards for the street lamps have already arrived. It is expected the works will be completed before the autumn.

DORCHESTER.—Authority has been given by the Town Council to their General Purposes Committee to consult Mr. F. M. Newton, of Taunton, as to the cost of providing the town with the electric light.

EDINBURGH.—A largely-attended public meeting of the ratepayers of the Calton Ward was held last week to consider the question of lighting the city by electricity. It was pointed out by one of the members of the Town Council that the time had come when urgency should be given to the matter, as the Provisional Order was imperilled by the delay which had already occurred. Ultimately, the meeting broke up without arriving at any satisfactory conclusion on the subject, a motion and an amendment only receiving about 50 votes. The object of the organisers of the meeting was to obtain the opinion of the ratepayers upon the decision of the Corporation to take the electric lighting into their own hands, and not to transfer its working to a local company.

ELECTRICITY IN MINING.—The New Zealand Government have authorised an important inquiry to be made as to the application of electricity as a motive power to gold-saving batteries, the current to be generated by means of a waterfall within a few miles of the "Quaotunu Field," where considerable difficulty has been experienced in saving the gold from the ores, owing to the cost of working the batteries. The ore is low grade. The Government have decided to send Mr. Fletcher, electrical engineer, and Mr. Gordon, their Inspector of Mines, to report as to what can be done in the matter.

ELECTRICAL TRADES' UNION.—We are informed that the annual conference of this Union will be held at the Black Boy Inn, Groat Market, Newcastle, during Whitsun week. The Union claims to have a membership of over 3,200, and in all 32 branches. On the 20th inst. there is to be a mass meeting of electrical workers at Newcastle which is to be addressed by Mr. Gooday, the general treasurer, on the subject of "A Legal Eight Hours Day and its Relation to the Unemployed."

GLASGOW.—The electric light at Free St. Paul's Church is now an accomplished fact. The work has been carried out by Messrs. MacLellan and Co. to the satisfaction of the pastor and congregation.

HARROGATE.—The borough surveyor and Mr. Wilkinson, consulting engineer, are preparing a scheme to lay before the Corporation with regard to the Electric Lighting Order. The matter is to be referred to the General Purposes Committee.

HENLEY.—Ferry Lodge, Wargrave, is to be lighted by the electric light, the contract having been placed with Messrs. Laing, Wharton and Down.

Digitized by Google

HOVE.—The Town Hall Committee of the Hove Commissioners, having further considered the offer sent in for wiring and providing fittings for lighting the Town Hall by electricity, have recommended the Commissioners to provide their own wires and fittings, and to apply to the Local Government Board for sanction to borrow £1,400 to meet the estimated cost of the work.

HOWRAH, INDIA.—Messrs. Martin and Co., in conjunction with Messrs. Burn and Co., are, we learn, preparing a scheme for lighting the streets of Howrah by electricity at an estimated cost of two and a-half lacs of rupees (nearly £17,000). Both public and private lighting are embraced in the scheme, which will shortly be submitted to the Municipal Commissioners of Howrah for approval.

ILFORD.—At a meeting of the Ratepayers' Association it was agreed that no sufficient reason had been shown by the Local Board why the proposal to adopt the electric light for the town had not been accepted, except in the fact that the interests of the local Gas Company were strongly represented on the Board.

KIDDERMINSTER.—Mr. A. Bromley Holmes, who was selected to advise the Law Committee on the subject of electric lighting, has advised the adoption of a low-tension direct-current system. He estimates the cost at about £15,000 for a station and plant capable of supplying 3,000 16-c.p. lamps, provision being made for an extension of the lighting subsequently. The Committee recommended that the usual circular be sent to probable users to enable them to estimate the demand for the light, for which it is proposed to charge 6d. per unit. As soon as the result of this circular is known the Committee will further report.

LAUNCESTON.—At the last meeting of the Town Council a letter was read from the Brush Company intimating their intention of applying for a Provisional Order to supply electricity for public and private purposes within the borough.

LECTURES.—Lectures on electricity and some of its varied applications have recently been delivered at Ipswich by Mr. Notcutt, B.Sc., at Hamilton (N.B.) by Mr. D. Hunter, at Sunderland by Mr. W. H. Flood, and at Dublin by Mr. Rochfort.

LEICESTER.—Some time back the question of lighting the extensive premises of the Leicester Co-operative Society came up for discussion and met with some opposition, but at a meeting just held a proposal by Mr. Harrott that the Society should itself provide an installation was only lost by one vote.

MIDDLESBOROUGH.—Three firms, including Messrs. J. H. Holmes and Co., of Newcastle, have been asked to send in offers for executing the necessary works in connection with the lighting of the Municipal Buildings and Town Hall of Middesborough.

NANTWICH—At the last meeting of the Local Board the Clerk stated that he had only received about a dozen replies to the circular sent out by the Electric Lighting Committee. It was decided not to renew the electric light contract for the Local Board Offices during the summer months.

NEWPORT.—Prof. Robinson has sent in his report dealing with the subject of the lighting of this town by electricity. He deals with the installation of the light into many of the principal thoroughfares, and estimates the cost of replacing the gas at about £30,560, and the annual cost of maintenance at about £5,650.

PONSONBY HALL.—Ponsonby Hall, the ancient seat of the Stanleys, has been fitted up with the electric light, the current being generated by a turbine driven by water obtained from the river Calder.

PORTRUSH.—With regard to the electric lighting scheme which has been prepared by Mr. H. W. Blake, the Town Commissioners have, before taking action, decided to appoint a committee to obtain definite information as to the amount of support likely to be given by the ratepayers. Under the scheme the estimated cost of buildings, plant, apparatus, &c., will be £6,230, excluding the cost of the site. The working expenses are estimated to reach about £500 per annum, and the yearly revenue about £800, at a charge of 7d. per unit.

RANGOON.—The engineer of the Rangoon Municipality has submitted a report on the proposal made by the Manchester Edison-Swan Company to light the streets of Rangoon by electricity. The Company proposes to supply 1830 24-c.p. lamps for 38,000 rupees per annum, a concession being granted to them for fifty years. The Company further proposes paying 5 per cent of the profits to the Municipality in lieu of rent for the necessary sites for generating stations, &c.

READING.—The Electric Lighting Committee having reported the steps taken in regard to the Electric Lighting Provisional Order before the Board of Trade, the Town Council have adopted the Committee's report. Under the arrangements now made, if the Council determine to purchase the undertaking of the Electric Lighting Company provision is made for all accounts of capital, expenditure, &c., to be available. The Committee were anxious to embody a clause in the Provisional Order absolutely specifying what system of supply should be adopted, but the Board of Trade objected to this, while agreeing to the insertion of words giving the Local Authority an opportunity of being heard before the Board of Trade sanction to any particular system was obtained.

REDDITCH.—It has been decided to employ an expert to advise the Local Board on the subject of electric lighting, the general opinion being that gas being both expensive and inferior in the district, electric lighting would have a very fair chance of success.

SHOREDITCH.—Mr. A. M. Sillar has been appointed by the Vestry Instructor to the electric fitting class at the Technical Schools at a fee of 10s. 6d. per lesson. Some time back it was decided that the question of granting applications for hydraulic power should be discussed concurrently with the laying of mains for the electric light. The Hydraulic Power Company are, however, anxious to commence operations, and the whole question has, therefore, been referred back to the Paving and Sewers Committee for further discussion.

SOUTHAMPTON.—The Local Government Board have given their consent to the Town Council to borrow £400 for the purpose of lighting the Free Public Library by electricity.

SOUTHGATE.—The Local Board has voted a small sum, to be spent in the purchase of apparatus and materials for use in teaching the upper classes in the local schools electrical subjects.

SOUTHPORT.—Mr. E. Manville has sent in his report upon the most suitable system for lighting the district by electricity, upon which a difference of opinion arose amongst the members of the Electric Lighting Committee of the Town Council. He recommends the alternating-current transformer system, which is in confirmation with the original recommendation of the Borough Engineer.

WORCESTER.—A motion has been placed on the paper by a member of the Board of Guardians, to rescind the resolution recently come to declining to adopt the electric light at the workhouse. It is probable that an isolated plant will ultimately be put down to light the buildings.

YARMOUTH.—The Local Government Board have been asked to grant power to the Town Council to borrow £15,000 on account of the electric lighting scheme.

PATENT RECORD

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

5,486. MESTON. Dynamo-electric machines.

COMPANIES' MEETINGS AND REPORTS.

Western and Brazilian Telegraph Company (Limited).

The twenty-fifth ordinary general meeting of this Company was held yesterday (Thursday) at Winchester House, E.C., Mr. W. S. Andrews (Chairman) presiding.

The SECRETARY (Mr. R. M. Cunningham) read the notice convening the meeting, and the minutes of the last meeting.

The CHAIRMAN said: Gentlemen, you have all had copies of the report and accounts, and I presume, you will take them as read. I am sorry to say that it is my melancholy task to-day to mention the death of a greatly esteemed gentleman, and one of the leading men in the telegraphic world, namely, Sir James Anderson, who was Chairman of the Brazilian Submarine Company with which, as you know, we are very intimately connected. Sir James Anderson was a very good friend of ours—in fact, I think he was a good friend to everybody. (Hear, hear.) He was a mellow, kindly-natured man who made troops of friends without, as I believe, making a single enemy. He was a man of considerable ability, and his loss will be a severe one, not only to his many personal friends whom he always possessed, but to the telegraphic world in general. Gentlemen, I must also mention something else of a personal nature before coming to the accounts. I daresay you notice the absence of our friend, Mr. Coppen, who was elected by the shareholders to a seat on the Board. He was unfortunately taken ill recently, and has had to go abroad for the benefit of his health. Before leaving, however, the accounts were in a rather forward state, and we were enabled to foreshadow pretty accurately what is being laid before you to-day, and Mr. Coppen desired me to say that he fully concurred in the policy which we were bringing before you in the report. After those preliminary remarks, I will now deal as usual with the receipts of the Company for the last half of 1892. The income was £86,954. 11s. 2d. against £92,345. 4s. 7d. for the corresponding half, showing a decrease of £5,390. 13s. 5d. on the six months. Considering the depres-

Digitized by Google

sion of commercial affairs in South America—not merely in one State, but in all the States—the condition of the exchange, and the additional competition we have been subjected to from October 5th to December 27th in last half-year, it appears to me that the figures, on the whole, are really more satisfactory than we could have anticipated. On the other side, the expenses are an encouraging feature, showing, as they do, a reduction on the total amount, partly owing to exceptional causes. They amount to £37,165. 11s. 5d., against £38,404. 5s. 1d., or a decrease of £1,238. 13s. 8d. Of course those totals are made up of a great many items. In abstract "A," for instance, there is an increase of £1,866. The expenses incurred under the head of salaries and wages in Brazil, where the revenue is earned, show an aggregate growth of £1,143, due to many causes. Our local superintendent and representative received an increase, and there is an item of £500 which will not occur again. There is also £575 for additional clerkage, duplex, promotion on account of long service, and certain small local additions owing to the lower value of the milreis in which those particular servants are employed. Then there is a sum of £870 caused by the changes in the staff, travelling expenses, and so on, which were unavoidable; and a small increase in the medical expenses and gas make up the total. On the other hand, there is a decrease of £743, mainly on the maintenance of land lines and stores and apparatus. There are small decreases in stationery and law and insurance, making up the remainder. The net result of the increase under abstract A is £1,886. The expenses of the ships in abstract B show a decrease under all the heads, the "Norseman" of £2,331 and the "Viking" of £793. As the ships were a shorter time at sea less coal was consumed, and the coal was purchased at a lower price. The "Viking" was under repair part of the period, so that her expenses were not running on, and there were some exceptional causes besides, giving as the result a total saving of £3,124. Under abstract C. the London expenses, you will find a total increase for salaries, rents, stationery, stamps, and telegrams amounting to £127. The net outcome of the whole thing is a reduction of £1,238 in the expenses of the Company for the past half-year. If we now take the balance of the revenue, £49,788, together with the sum brought from the June half-year, £1,662. plus the dividend from the Platino Company, £7,387, because I am glad to say we have got our dividends back from the Platino, we reach a total of £58,838. Against this there are charges for the debenture interest £12,426, redemption £6,674, and reserve £15,000, together £34,100. This leaves us £24,738, and we propose to recommend the declaration of a dividend of 1½ per cent. for the half-year, at the rate of 3 per cent. per annum. This will take about £21,908, leaving £2,829 to be carried forward. Now, I am glad to say that we seem to have reached a demarcation line, so to say, in the history of this concern. We have been aiming at particular things, including the duplication of our system from Pernambuco to Buenos Ayres, and we have succeeded in getting that done. It was a necessary preliminary to getting rid, as we hope to do, of one of your repairing ships and of the consequent expense. After we had obtained the duplex and had removed all the cable we had in deep water, we saw our way to ordering the new ship we have just sent out. It has been built upon the best lines, with the highest speed and working capacity, and we trust she will enable us to maintain our system more economically. At the present moment, as you know, we have the old "Norseman," the "Viking," and the new "Norseman." The new ship was built with the special object of keeping our whole system in a state of efficiency without the aid of a second ship. She has now gone out, and on her arrival the "Viking"—which is the vessel at present on the station—will be laid up. The ship will be maintained in good condition, a captain and engineer will be retained, and in the event of an exceptional emergency, which we do not anticipate, she would be ready almost at once to go to sea. Well, we are going to give this policy a trial, although not too long a one. The "Viking" will cost very little when laid up, and we expect that the result will be satisfactory, and that we shall be enabled to do away with the large expenditure necessarily attendant upon keeping two ships instead of one. The "Viking" is in first-rate order. She has new boilers and excellent machinery, and if we can see our way to do without her it is our intention to dispose of her at the best price possible. The former "Norseman" is actually laid up, and we are only awaiting an opportunity to sell her or to obtain a charter for her. She is a fine vessel, and can handle cables in very deep water. There is, however, one circumstance against it, and it is a strong one, unfortunately. I refer to the present state of the market. We can only hold on and endeavour to do the best when an opportunity arises. Well, gentlemen, we told you that if the revenue continued fairly satisfactory, and especially if the exchanges were good, we should be enabled to meet our liabilities without issuing any debentures. As a matter of fact, we have so far been able to do so. Neither circumstances nor exchange have been very propitious, but, nevertheless, we have managed to get through. I daresay some gentlemen have noticed that we have put £15,000 to reserve fund. I know that some gentlemen object to the amounts we place to reserve, but in this case, again, it has been Hobson's choice. You had approved of the loops policy and the ship policy, and it is the carrying out of these things which, as all of you know, has required the money for the payment of them. Our accounts are all straight up to December last, but we knew there were some still to come in which would have to be provided for—mostly on account of the new ship, which is going to bring about the big economy I have mentioned. Of course, we have no shares to issue but only debentures. You are aware that it was decided we should avoid issuing these debentures if possible, inasmuch as they would only put permanently a charge between the ordinary and deferred shareholders and a dividend, and therefore we had to take from income the £15,000 I have named to provide for the engagements we had entered into, as we believe, for your future benefit. We have scraped through, notwithstanding the fact that the conditions have not been as good as we anticipated they would be. It was then quite uncertain to what extent the competition, then threatened, would deplete our revenue. We told you we should do our best, and we thought that, owing to the enlightened assistance of you, gentlemen—because we could not have done it without that—owing to this, and to the looping of the cables, and the provision of the duplex, and all the various other arrangements made, we should be able to hold our own. Well, looking at the traffic of 1892, I think it will be admitted that we have fairly held our own there; and if we look at the current traffics, those published from time to time, I think you will say that we are holding our own still in 1893. I confess, personally, that I entertain the view that we are doing very well under the circumstances. We are not losing what we might reasonably have anticipated we should have lost, and our revenue is keeping up, not merely in face of this competition, but it is keeping up in face of the low exchange also. The exchange has been unusually low, and presses upon us very severely. I think I may go as far as to say that, notwithstanding all this competition, all we need, even with our present business—and you know it is a business we are getting under depression, and that the state of things in the River Plate and in Brazil is very unsatisfactory, and that trade is comparatively inactive—well, even with the trade we are getting under these circumstances, if the exchange were only, I will not say at par, but fairly favourable, our Company would be enabled to pay the dividends which it did recently pay. All that we want at the present time—provided, of course, nothing of an exceptional character arises, which cannot be foreseen—is a rise in the rate of exchange, and given that, there is no earthly reason why this Company should not be as prosperous as in those days which we talked of as showing abnormal traffics. My impression is that we should then get back somewhere to that position, at all events in the money. They say there is a grand coffee-crop in Brazil, and it is withdrawing a considerable amount of currency, which Brazil at the same time destroys, and by that means we hope exchange may be improved. Then, if exchange does improve, there may take place a great recovery in the commercial affairs of the young and enterprising nations of South America. They are big nations, and are always developing and increasing their commerce. In fact, we are dealing here with a growing quantity. Now, gentlemen, I do not think I need trouble you with further observations, and therefore I beg to move—

"That the report and accounts to the 31st December, 1892, be and are hereby approved and adopted, and that a dividend on the ordinary shares of 4s. 6d. a share, free of income tax, making with the interim dividend 2½ per cent. for the year 1892, be and is hereby declared payable on the 12th instant."

Mr. C. W. EARLE seconded the resolution.

In reply to Mr. CLARKE,

The CHAIRMAN said the £6,000 from the Brazilian Submarine Company was included in the accounts.

In reply to several shareholders,

The CHAIRMAN said: The figures give the gross revenue after deducting the exchange. I omitted to mention that the new ship was paid for out of the balance of the reserve that we brought over to this current period.

The resolution was then carried unanimously.

Lord RICHARD BROWNE proposed the re-election as a director of Mr. W. S. Andrews.

Major WOOD (Managing Director), in seconding the resolution, said the Chairman gave an immense amount of time and trouble to the affairs of the Company, and brought to bear upon their business that practical knowledge which was perfectly invaluable.

The motion was agreed to.

The CHAIRMAN then proposed the re-election of Mr. J. Coppen as a Director.

Mr. D. H. GOODSALL seconded, and it was passed.

On the motion of Mr. ELLIS, seconded by Mr. PETO, the retiring auditors—Messrs. Turquand, Youngs, Weise, Bishop, and Clarke, and Messrs. Deloitte, Dever, Griffiths and Co., were re-appointed.

A vote of thanks to the Chairman, Directors, Managing Director, Secretary, and Staff, proposed by Mr. PETO, and seconded by Mr. MACHELL, brought the proceedings to a close.

Elmore's (French) Copper Company (Limited).

An adjourned general meeting of this Company was held on Monday last at Winchester House, E.C., Major C. Jones presiding.

The meeting was called for the purpose of obtaining the shareholders' consent to the Company going into voluntary liquidation, and to enable Mr. Duncan (Receiver) to enter into an agreement for the sale of the factory and business in France to M. Secrétan, as representing a French Company, on the lines set forth in the scheme submitted to the shareholders a few weeks since, the chief points of which will be found in *The Electrician*, of April 14th.

Mr. DUNCAN said the arrangement was not all that he could have wished, but it was the best he could obtain, on account of the requirements of French law. With regard to the creditors, the debenture-holders would be asked to extend their claim for five years, and the Elmore's Foreign and Colonial Company to postpone their second mortgage and make it a third mortgage, in order that the creditors who had securities might be satisfied by being put in the position of second mortgage-holders.

Mr. WOOD (Chairman of the shareholders' Committee) moved a resolution agreeing to the sale, and stated that the shareholders would now have a chance of eventually getting a return of their capital.

The motion was carried.

Resolutions for the voluntary liquidation of the Company were agreed to, and Mr. Pixley was appointed liquidator.

Elmore's German and Austro-Hungarian Metal Company (Limited).

The second annual general meeting of this Company was held on Wednesday last week, at Winchester House, Old Broad-street, E.C., Mr. James Rock presiding.

The SECRETARY read the notice convening the meeting.

The CHAIRMAN said: The meeting that day was one of great importance to the future of the Company. It was for them to say whether they should press on with the enterprise. He unhesitatingly said they ought to go on with it, and be content with nothing less than a complete commercial success. From a practical point of view, their methods of manufacture, under the able management of Mr. Preschlin (their manager at Schladern), had made extraordinary progress during the last three months. He was not at liberty to speak fully upon all points, from considerations of prudence, but it was his conviction that if the same conditions which they now had at their works had existed a year or two ago, they would not be asking for money that day, and the whole Elmore enterprise might have had a very different complexion from that which it then had. He claimed for their Company a distinct individuality. They were not mixed up with any other company, but had established a firm basis for success in the future, so far as it depended upon a well-organised manufactory in which the methods of working had been so developed as largely to increase the accuracy of the work and to diminish the cost of production. The year 1892 was one of difficulties. For many months they were kept out of the mandrils which had been ordered from the English Company, and the remainder of the year was chiefly employed in making mandrils for themselves. The result of the only appeal for funds made to their shareholders was shown by the report they had. By the failure of the issue of preference shares the Board was placed in a very difficult position—the last instalment of the purchase of the property at Schladern was nearly due, and there were no funds in hand to meet it or to carry on the works. In this emergency they applied to Mr. Berger (the vendor of the property) to allow further time for payment, and he extended the time till November next. Some money must be provided immediately, or the works must be closed. The debts owing to outside creditors by the German Company on December 31st were small, and there was then cash in hand sufficient to pay them.

The CHAIRMAN then entered into a detailed account of the "mandril troubles" the Company had passed through and surmounted. Continuing, he said their present funds would only carry them on a week or ten days longer. They proposed to arrange for an issue of mortgage debentures secured upon the property at Schladern, but this would take time and would not meet the present emergency. They had £3,000 of debentures charged upon the property of the Company, including £50,000 in shares of the Company in Germany, and the Directors asked the shareholders to subscribe for these. They were secured upon all the property of the German and Austro-Hungarian Metal Company. £1,000 would enable them to go on till the end of this month; £2,000 would carry them on till the end of June, and give them time to turn round and endeavour to find the larger sum required to complete the purchase of the property; with £3,000 they could press on the business with greater probability of early success. He then moved the adoption of the report and accounts.

Lieut.-General G. H. FRASER seconded the motion.

General BEADLE said they were asked to subscribe a small sum in order to put what really appeared to be a very promising young factory into better working order; but before doing so they wanted to understand a little more about the Company. The Board had gone to allotment with an insufficient amount of capital subscribed. Seventy-five thousand shares were offered to the public under the promises of a prospectus every paragraph of which appeared to him to be unfair and misleading. The prospectus said that they were to commence with a working capital of £100,000, but only £50,000 of the shares had been applied for, and therefore the Board should have returned the money. The result was that they were now compelled to raise more money from the public. No doubt steps had been taken to bolster up the shares, and the whole of that matter would have to be gone into most carefully by a committee. He concluded by moving an amendment—

"That this meeting be adjourned, and a committee of shareholders be appointed to report generally."

He thought it right that the affairs connected with the Company should be inquired into.

Mr. GLADSTONE seconded the amendment.

Mr. F. L. RAWSON stated that the Directors of the Austro-Hungarian Company fixed £50,000 as the minimum amount for going to allotment before the Company came out.

The CHAIRMAN said the important question was as to the working capital. If General Beadle would look at the prospectus he would see that it was stated that if the whole of the capital were subscribed there would be £100,000 for working capital; but, unfortunately, that amount was not subscribed. Before the prospectus was issued the Board decided, on the motion of Mr. John Morris, that they would not go to allotment unless they had as much working capital as the French Company, namely, £50,000, which they thought was sufficient. If the amendment were carried, and the meeting were adjourned until May 31st, their works would be closed for want of funds.

Mr. F. L. RAWSON suggested that the best course to pursue was for the Board to issue £5,000 of debenture stock, charged upon the property in Germany.

The CHAIRMAN stated that the Board had no objection to an investigation of the affairs of the Company, but unless money were found in ten days the works would have to be stopped.

The amendment was then put and lost, and the adoption of the report was agreed to.

On the motion of Mr. McFARLAN, Mr. Rock was re-elected a Director of the Company.

The retiring auditors were re-appointed, and a vote of thanks to the Chairman terminated the proceedings.

West India and Panama Telegraph Company (Limited).

The following is the report of the Directors for the half-year ended December 31st last, to be submitted to the thirty-second ordinary general meeting to be held at Winchester House, E.C., on Tuesday, the 16th inst.:—

The amount to the credit of revenue is £38,358. 11s. 9d., against £36,141. 2s. 8d. for the corresponding half-year of 1891, and the expenses have been £25,155. 11s. 5d., against £25,296. 3s. 11d. for the same period in 1891, leaving a balance of £13,203. 0s. 4d., which, with £3,704. 15s. 2d. brought from last account, makes a total of £16,907. 15s. 6d. Of this sum the Directors have placed £1,500 to reserve, leaving an available balance of £15,407. 15s. 6d., with which it is proposed to deal as follows:—

	£	s.	d.
First Preference shares—			
Dividend, six months to Dec. 31st, 6s. per share ...	10,368	18	8
Second Preference shares—			
Dividend, six months to Dec, 31st, 6s. per share ..	1,400	14	0
Ordinary shares—			
6d. per share (free of income-tax)	2,208	0	6
Balance to current half-year's account	1,430	3	0
	15,407	15	6

The traffic receipts for the six months show an increase of £2,065. 7s. 1d., as compared with the corresponding period, which is solely due to greater activity in West India trade. The cost of repairs to cables amounted this half-year to £12,013. 7s. 3d., as compared with £15,055. 18s. 2d. for the corresponding period.

The Company's s.s. "Grappler," after having been repaired and fitted with a new boiler in London, arrived in the West Indies with a cargo of 256 nautical miles of cable for stock on the 23rd ultimo.

Since the close of the half-year the Directors have to report that the colony of Trinidad, whose ten years' term of subsidy of £6,000 per annum expired on December 31st last, has reduced its grant to £3,000 for 1893, and that St. Lucia has also reduced its subsidy from £800 to £500 for the current year.

The Directors feel that these curtailments of subsidies, following as they do so shortly after the Company has made the sacrifice of largely reducing rates, cannot be looked upon but as a heavy blow to the anticipations of some improvement in the return on the capital invested in an enterprise which, for the last twenty years, has done so much for the commerce, the safety, and the administrative economies of the West India Colonies, and so little for the shareholders.

Mr. William Andrews retires at this meeting, and offers himself for re-election. Mr. John George Griffiths, the auditor, also retires, and offers himself for re-election.

The following circular accompanies the report:—

The Directors regret to announce the death of their esteemed colleague, Sir James Anderson, which has occurred since the accompanying report was in print. For the reasons stated in the Directors' report presented to the last ordinary general meeting, it is not proposed to fill up the vacancy in the Board thus occasioned. As, however, the Articles of Association fix the minimum of Directors at six, and there now remain but five Directors on the Board, it is necessary to obtain the sanction of the shareholders in general meeting to an alteration of this minimum. It is therefore intended at the extraordinary general meeting, of which notice is endorsed hereon, to propose to the shareholders that the minimum number of Directors shall, until otherwise determined, be four instead of six.

LEGAL INTELLIGENCE.

Ipswich Electricity Supply Company (Limited) v. Iliffe.

On Tuesday, in the Queen's Bench Division, before Justices Cave and Lawrence, an application was made by Mr. Ashton Cross on behalf of Messrs. Bolton and Sons, Birmingham, judgment creditors of the Acme Electrical Works, which have been taken over by the Ipswich Company, the plaintiffs in this action. Mr. Justice Mathew, in chambers, had made an order in April last ordering the Receivers of the Company to pay certain moneys to the applicants subject to the satisfaction of any prior rights, and introducing certain other limitations which the applicants wished to have removed. Mr. Cross said there was no evidence given of any prior charges or rights, and the manner in which the receivers were appointed made it clear that the real object was to protect the works and goods of the Company from the creditors. Messrs. Bolton and Sons had supplied goods to the Acme Electric Works, and they were not made aware of the fact that the works had been transferred to anybody else until quite recently, when they were informed that Messrs. Teague and Aiken had been appointed Receivers to the Company, in consequence of internal disputes between the partners. Mr. Iliffe had been the original owner of the works, but the Ipswich Electricity Supply Company had been formed, with a capital of £100, of which £7 had been subscribed, to purchase them, the consideration, as disclosed by the agree-

Digitized by Google

ments filed at Somerset House, being £30,000, to be paid by the allotment to the vendor or his nominees of £10,000 in debentures, £10,000 in Five per Cent. Preference Shares, and £10,000 in ordinary shares, the sale to take effect as from August 1st. Arrangements were made, however, whereby the works should still be carried on in the same name—that of the Acme Electric Works. The debt of Messrs. Bolton was about £99, and they obtained judgment against the Acme Electrical Works; but when they tried to levy execution they were met by the statement that an action had been brought by the Ipswich Company against Mr. Iliffe, the vendor, and that Messrs. Teague and Aiken had been appointed joint interim Receivers and managers. There was another subsequent order, by which a gentleman, who appeared to be a judgment creditor of Mr. Iliffe, had appointed himself Receiver in regard to Mr. Iliffe's interest in the property. Applicants' writ was issued against the Acme Works on March 1st, judgment obtained on March 10th, and, the Receivers meeting the claim in the manner stated, after some litigation an order was made on April 7th, "that the Receivers hold the goods until further order, the plaintiffs (Messrs. Bolton and Sons, the execution creditors) to apply forthwith to the Court to direct the Receivers to pay the judgment debt." The application was made, and the result was the order of Mr. Justice Mathew of April 26th. His (Mr. Cross's) application was that the debt should be paid within seven days, or that he should have leave to issue execution.

Mr. JUSTICE CAVE said they could not fix a time within which payment must be made, and there being no opposition from the Receivers, Mr. Justice Mathew's order was amended, so that the applicants have a charge on the moneys of the Company subject to any prior charges, the Receivers to pass their accounts within a reasonable time.

Suren, Hartman and Co. v. W. T. Henley's Telegraph Works Company, Limited.

In the Court of Appeal, on Monday, before Lords Justices Lindley, Bowen and Kay, an appeal from a judgment of Mr. Justice Stirling, on behalf of the defendants in this action was heard on Monday last. The matter in dispute was as to the construction of a clause in an agreement between the parties. In the year 1886, the International Cable Company was formed to lay down submarine cables, that Company having obtained a concession from the Government of Portugal for leave to lay down cables to Canada *via* the Azores, the concession and monopoly to last for twenty years. On November 2, 1886, the International Cable Company entered into a contract with the defendant Company under which the latter were to manufacture a large amount of cable. Soon after this a contract was entered into between the plaintiffs and the defendants, the undertaking being that the plaintiffs should take 500 shares in the International Cable Company, paying £250 on application and £250 on allotment, but that the defendants should indemnify the plaintiffs against the payment of any further calls on those shares, and should within two months of receiving an order to manufacture all or any of the cables repay the plaintiffs the full amount which they had paid upon the shares, either in cash or fully paid-up shares. The order to manufacture had never been given, and the plaintiffs sought to recover the £500 which they had paid. The defendants contended that their payment of the money was to be contingent on the order being given for the manufacture of the cables, and as no such order was ever given they were not liable. Mr. Justice Stirling held that they were, and defendants appealed from that judgment.

Mr. RAM, for the plaintiffs, contended that by the terms of the contract they were not called upon to repay the £500 on the shares unless they got the order for the manufacture of the cables: and in reply to the Lords Justices as to the consideration which the plaintiffs were to receive for their payment, said it was a joint risk entered into in the expectation of considerable profits, Messrs. Suren, Hartman, and Co. expecting to supply the wire required for the cable.

Lord Justice LINDLEY said it was obvious that the plaintiffs took the shares simply as the trustees for the defendants, and at once handed them over. The clause as to the repayment within two months of the order being given was merely a statement of the time for the repayment and a stipulation that the defendants, in the event of an order being given, should have the option of making the repayment either in cash or in fully paid-up shares. He could not for the life of him see how the defendants could on the agreement raise the contention which they did. It would be monstrous if they were not to pay the £500.

Lords Justices BOWEN and KAY concurred, and the appeal was dismissed with costs.

Gartside v. Shippey.

At the Manchester Spring Assizes, before Mr. Justice Collins, without a jury, an action was brought to recover the sum of £56. The plaintiff was Mr. Henry Gartside, brewer, of Stalybridge, and the defendant was Mr. Arthur Shippey, electrical engineer. The parties were interested in the success of a patent brake and starter, and the plaintiff agreed that in the event of the Manchester Carriage and Tramways Company adopting it on their tramcars he would pay the defendant £1,000. The patent was tested, and was said to be a complete failure. On one occasion the plaintiff lent the defendant £56, and this he now asked to be repaid. The defence was that the money was to be repaid out of the problematical £1,000. This the plaintiff denied; he said the defendant asked that the arrangement for repayment might be so, but he declined to allow that, and the defendant accepted the loan on his own personal account. Mr. Shippey claimed that his patent had not proved a failure, and that, therefore, he was entitled to £1,000 from the plaintiff, and for this sum he counter-claimed.

The Judge found for the plaintiff on both the claim and counter-claim.

NEW COMPANIES, STATUTORY RETURNS, &c.

[In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in "The Electrician" Electrical Trades' Directory and Handbook, 1893, pages 320-348, &c., &c.]

COLNE ENGINEERING COMPANY (LIMITED).—This Company was registered on the 5th inst. with a capital of £10,000 in £1 shares, to carry on the business of mechanical and electrical engineers, electricians, millwrights, art-metal workers, &c., carried on at Twickenham.

ROLLASON'S WIND MOTOR COMPANY (LIMITED).—This Company was registered on the 5th inst., with a capital of £35,000 in £1 shares, to carry on the business of electricians, mechanical and electrical engineers, suppliers of electricity for the purposes of light, heat, motive power, or otherwise, and manufacturers of and dealers in all electrical apparatus.

ST. NICOLAS CONSTRUCTION COMPANY (LIMITED).—This Company was registered on the 2nd inst., with a capital of £40,000, divided into 2,000 shares of £20 each, to carry on the manufacture and sale of electric, telegraphic, and scientific instruments, the erection, maintenance, sale, and letting on hire, of electrical, engineering, and other goods and apparatus connected with the production of light, heat, sound, and motive power, and to carry on the business of electricians, electrical contractors, electrical, mechanical, chemical, and metallurgical engineers, suppliers of electricity, and manufacturers of and dealers in all electrical apparatus.

SAXBY AND FARMER (LIMITED).—This Company was registered on the 4th inst., with a capital of £25,000, in £10 shares, to carry on the business hitherto carried on by Messrs. Saxby and Farmer, and generally to carry on the business of manufacturers of railway signals, locking apparatus and safety appliances, mechanical and electrical engineers, electricians, iron and brass founders, &c.

THOMAS ROBINSON AND SON (LIMITED).—Registered with a capital of £120,000 in £10 shares, to carry on business as engineers, boiler makers, millwrights, machinists, &c., at the railway works, Rochdale.

BRITISH TANNING COMPANY (LIMITED).—A resolution was passed at a meeting held on May 3rd at Winchester House that the Company be wound up, and Mr. John Dalgleish, chartered accountant, of 8, Old Jewry, E.C., was appointed liquidator.

CONSOLIDATED TELEPHONE CONSTRUCTION AND MAINTENANCE COMPANY (LIMITED AND REDUCED).—A petition for confirming a resolution reducing the capital of this Company has been presented to the High Court of Justice.

ELECTRICAL SUPPLIES AND FITTINGS COMPANY (LIMITED).—The petition of the Electrical Company (Limited), directed to be adjourned from April 11th, will be heard on Wednesday next, May 17th, when the Court will be asked for an order continuing the voluntary winding up under the supervision of the Court.

INDIA-RUBBER, GUTTA-PERCHA AND TELEGRAPH WORKS COMPANY (LIMITED).—The annual return of this Company, made up to February 28th, has been filed recently. The whole nominal capital of £500,000, in £10 shares, has been taken up, the full amount called, and all calls paid.

LONDON METALLURGICAL COMPANY (LIMITED).—A petition for the winding-up of this Company was presented on May 6th, and is down for hearing at the Royal Courts of Justice on Wednesday next, the 17th inst.

NEW BRITISH ELECTRIC INSTALLATION CONTRACTORS (LIMITED).—At extraordinary general meetings, held at 50, Foregate-street, Worcester, on March 11th and April 8th, the following special resolution was duly passed and confirmed:—"That this meeting authorises the issue of £3,500 in £6 per Cent. First Mortgage Debentures, redeemable in seven years from the 25th day of March, 1893, such debenture issue to form part of, and not an addition to, the amount of capital authorised by this clause, viz., £25,000."

NEW TELEPHONE COMPANY (LIMITED).—The annual return of this Company, made up to January 14th, has been filed. The nominal capital is £750,000, divided into 74,700 shares of £10 each and 3,000 shares of £1 each. 74,695 £10 and all the £1 shares have been taken up, and upon 1,000 £10 shares the full amount has been called; upon the £1 shares the full amounts have been called, and upon 75,200 £10 shares £4 per share has been called. The calls paid amount to £304,736, £1,064 is in arrears, 500 £10 shares have been issued as fully paid, and £10 has been paid on five forfeited shares.

NOTTING HILL ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return of this Company, made up to April 10th, has been filed. The nominal capital is £100,000, divided into 6,452 ordinary, 550 founders', and 2,998 ordinary preference shares of £10 each. All the ordinary and founders' and 816 of the ordinary preference shares have been taken up, the full amounts called, and all calls (£78,180) paid.

PORTLAND ELECTRIC LIGHT COMPANY (LIMITED).—In response to official inquiries, Messrs. Strode and Co. state that no business has ever been carried on by the Company, and that no opposition will be raised to the striking of its name off the register of joint-stock companies. The Company was registered on November 30, 1887, with a capital of £45,000, in £5 shares, to carry on the general business of an electric light and power company, but the shares taken up by the signatories to the Memorandum of Association were the only ones ever subscribed for.

Digitized by Google

SHEFFIELD TELEPHONE EXCHANGE AND ELECTRIC LIGHT COMPANY (LIMITED).—A meeting is to be held at the office of the Sheffield Electric Light and Power Company (Limited), Commercial-street, Sheffield, on June 12th, at 11, to receive an account of the winding up.

TAYLER-SMITH ELECTRIC COMPANY (LIMITED).—The first annual return of this Company, made up to August 3, 1892, has been filed. Out of a nominal capital of £6,000, divided into 300 preference and 300 ordinary shares of £10 each, 299 preference and all the ordinary shares were taken up, of which the ordinary shares were issued as fully paid. Upon the preference shares £7. 10s. per share has been called, resulting in the payment of £2,715 (including calls paid in advance), leaving £132. 10s. in arrears. The annual return for 1893, made up to April 1st, has also been filed, and shows that the full amount has been called on the preference shares, resulting in the payment of £2,980.

THOMPSON, RITCHIE AND CO. (LIMITED).—The annual return of this Company, made up to April 13th, has been filed. The nominal capital is £5,000, divided into 200 preference and 300 ordinary shares of £10 each. All the preference and 140 of the ordinary shares have been taken up, of which 100 preference and 70 ordinary shares have been issued as fully paid to Arthur S. Grove, the vendor. Upon the remaining 100 preference and 70 ordinary shares the full amounts have been called and all calls (£1,700) paid.

CITY NOTES, &c.

AFRICAN DIRECT TELEGRAPH COMPANY (LIMITED).—Notice is given of the drawing of 106 of the Four per Cent. Mortgage Debenture Bonds of £100 each of this Company, which will be paid off at par on July 1st at Parr's Banking Company and the Alliance Bank (Limited), Batholomew-lane, E.C.

AFRICAN TRANSCONTINENTAL TELEGRAPH COMPANY (LIMITED).—The following letter has appeared in *The Times*:—"The Central African and Zoutpansberg Exploration Company (Limited), Portland House, Basinghall-street, London, E.C. In a recent issue I notice that a general meeting has been held of the African Transcontinental Telegraph Company, at which it was stated that material was being sent to the Chinde for the purpose of constructing a line between Fort Salisbury and Zomba, presumably across Portuguese territory. In article XI. of the Anglo-Portuguese Treaty of June 11, 1891, we find as follows:—'It is further understood that in the above-named districts each Power shall have the right, so far as may be reasonably required for the purpose of communication between territories under the influence of the same Power, to construct roads, railways, bridges, and telegraph lines across the district reserved to the other. The two Powers shall have the right of acquiring in these districts, on reasonable conditions, the land necessary for such objects, and shall receive all other requisite facilities. Portugal shall have the same rights in the British territory on the banks of the Shiré and in the English territory comprised between the Portuguese territory and the banks of Lake Nyassa. Any railway so constructed by one Power on the territory of the other shall be subject to local regulations and laws agreed upon between the two Governments, and, in case of differences of opinion, subject to arbitration as hereinafter mentioned.' Surely this does not mean that, without any warning, the workmen of the Transcontinental Company are to land where they like in Portuguese territory, without any previous intimation, and proceed to erect a telegraph line, nor yet that, if a line is about to exist across this territory, it will be permitted to construct another and a rival line. The Portuguese Government has under construction, from Sena to Sete, a line of telegraphs, and a concession has been granted to the Companhia da Zambesia to construct certain telegraph lines in the province of Quilimane, and among these lines is that one destined to connect the lines coming to the Portuguese frontier, either on the north or south side, with those on the opposite frontier. If that concession is carried out, the Transcontinental Telegraph Company will be without a reason for demanding the right to enter upon or traverse Portuguese territory. There is no desire on the part of the Companhia da Zambesia, or those to whom it has intrusted the construction of the telegraph lines in question, to oppose or be hostile to the Transcontinental Telegraph Company—it wishes to work in harmony with them and to aid in the undertaking; but it maintains, and will maintain, that the right to construct the section of the line across Portuguese Zambesia is theirs, and, as they intend to exercise it immediately, there is no reasonable condition unfulfilled which, by Article XI. of the treaty, would entitle anyone to construct a competing line.—V. Lovett Cameron, Chairman, London Committee, Companhia da Zambesia.

CALLS DUE.—*May 15:* BRUSH ELECTRICAL ENGINEERING COMPANY (LIMITED), £1 on 10,000 new ordinary £3 shares, and 10s. on 15,000 new 6 per cent. preference shares of £2 each; CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED), final £2 on 20,000 Accumulative Six per Cent. preference shares of £10 each; ELECTRIC CONSTRUCTION CORPORATION (LIMITED), final £3 per bond on 10,000 Six per cent Second Mortgage Debenture Bonds of £10 each.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended May 7th were £793, as against £802 for the corresponding period of last year, being a decrease of £9. The total receipts for the half-year amount to £16,153, against £14,898 in the corresponding period of 1892, being an increase of £1,255.

CONSOLIDATED TELEPHONE CONSTRUCTION AND MAINTENANCE COMPANY (LIMITED).—At a special Board meeting on Tuesday, it was resolved, subject to audit, that dividends at the rate of 6 per cent. per annum on the preference and 2 per cent. per annum on the ordinary shares, both less income-tax, should be declared for the year ended March 31st at the approaching annual general meeting of the shareholders. The transfer books will be closed from the 19th to the 27th instant, both inclusive.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—In addition to the death of their Chairman (Sir James Anderson), the Directors and staff of this Company have to deplore the loss of Mr. Herbert Renny Duke (for many years auditor of the Company's accounts), who died very suddenly on May 3rd, and was buried at Shooter's-hill on Saturday last, the 6th instant.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this Company for April amounted to £20,800, and from January 1st to April 30th to £84,000. In the corresponding months of 1892 and 1891 the amounts were £82,800 and 88,000 respectively.

NEW SHANGHAI ELECTRIC COMPANY (LIMITED).—At the fifth ordinary general meeting of this Company, held at Shanghai, the Chairman (Mr. R. M. Campbell) said the working account showed they had made about Tls.500 more than they did last year, on a capital which had been increased by Tls.15,000, which had been borrowed at 7 and 8 per cent. This money was used specifically for the purpose of buying new incandescent plant of the latest and best type; it might have been better if they had been able to raise this additional amount. As things were at present in Shanghai, the Directors had made the best arrangements they could for carrying on the Company. The question of capital was really what bothered them most. As they went on developing and increasing their plant more capital was necessary, which they found it difficult to raise. The new machinery had only been erected during the last quarter of the year, but satisfactory increase had been the result of its erection. The Directors could at this moment employ immediately Tls.100,000 at a very profitable rate of interest, if they could only get it. During the time the Company had been working they had been fortunate in having a man like their superintendent to look after the Company's works, but he felt it to be a risky thing to have only one man at the works, and they had now got another man who was strongly recommended by their superintendent. Regarding arc lighting, that had not increased so much as they hoped it would have done. The Directors were authorised to pay a dividend at the rate of Tls.7 per share, and to deal with the balance as recommended in the report. Mr. R. M. Campbell was re-appointed a Director, and Mr. R. F. Eastlack auditor.

WELLINGTON (NEW ZEALAND).—The local gas company have resolved to amend their Memorandum of Association to enable them to deal with the subject of electrical supply,

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended May 5, 1893, after deducting 17 per cent. of the gross receipts, payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,849.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED.)—The receipts for the two weeks ended April 30th were £3,624, as compared with £2,656 for the corresponding period of last year.

WOODHOUSE AND RAWSON UNITED (LIMITED).—The following circular has been issued by Mr. F. D. Leslie (Receiver and manager) to the holders of First Mortgage Debentures and Debenture stock:—"In March last I was appointed by the Chancery Division of the High Court of Justice, Receiver and manager of this Company, on behalf of all the debenture and debenture stockholders, and since that time I have been endeavouring to arrive at the position and prospects of the undertaking, and to satisfy myself as to what would be the most advantageous course to pursue in the interests of the debenture holders and other secured creditors. I may say that I found the accounts in such a state that it was extremely difficult to arrive at either the amount due to the Company or its liabilities. I am now, I trust, succeeding in bringing the accounts into a satisfactory shape. There are so many branches and agencies spread all over the world that it is almost an impossible task in something less than two months to get at the true position of the whole undertaking. I have, however, with the sanction of the Court, despatched an agent to Africa, who will investigate the position there and look after the assets to the extent of over £20,000, which the books of the Company show are at Johannesburg and the other South African agencies. I have taken steps to preserve the assets in Sydney, and to settle the difficulties with the Barcelona and Milan agencies. I have closed down the Bristol branch and Hamburg agency, and am gradually doing likewise with the Cadby Hall works. I have reduced the expenses at head office on account on salaries, wages and rent at the rate of over £4,000 per annum. I have obtained leave to collect the debts due to the Company on behalf of and for the benefit of all the debenture and debenture stockholders, and to deal with the outstanding calls in the same way, except so far as they are specifically pledged as security for previous advances, and I have generally, so far as I have been able, done all that I can to keep the business alive and preserve the estate for the benefit of those who are entitled to it. It is very difficult to estimate what the various classes of debenture holders may reasonably expect from a realisation of the estate, because so much depends upon the way in which it is realised. Speaking with considerable doubt, I am inclined to think that the first mortgage debenture holders and the secured debenture stockholders (issued in December, 1892) may expect to be paid in full, but as to the debenture stockholders (5½ per cent.), I have very little doubt that unless some reconstruction scheme is proposed and carried through they will be considerable sufferers by the unfortunate stoppage of the Company. As to the feasibility of reconstruction and the proposals which are, I am told, about to be made, it is quite impossible for me to speak until some scheme in a concrete form is

Digitized by Google

offered for the approval of the various classes of creditors. As soon as this is done (if at all) I shall consider it my duty to study the same, and to advise to the best of my ability the debenture stockholders whose collective interests I now represent. I shal at all times be anxious and ready to give every debenture and debenture stockholder all the information in power."

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The receipts the week ended May 5th were £2,847.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 783.—Vol. XXXI. FRIDAY, MAY 19, 1893. PRICE FOURPENCE.
Annual Subscription (U.K.), 19/6

NOTES.

In his well-earned promotion from the secretaryship of the Railway Department of the Board of Trade to the Permanent Secretaryship of that ever-growing Government office, Sir Courtenay Boyle will, we feel sure, carry with him the best wishes of the electrical industry. The Act of 1882 was nothing more than a legislative skeleton, the vital details of which had to be filled in by the Board of Trade in addition to carrying out the work of administration. To meet the wishes of Parliament and safeguard the public without at the same time altogether stifling a struggling industry, was a hard problem even for permanent government officials, and the measure of success which has attended the efforts of the Board of Trade is largely due to the tact and "plain good intention" of the new Permanent Secretary.

It is to be hoped that with a set of new engines and dynamos, an elaborate condensing plant, a second line of trunk mains, and a fresh lot of house transformers, the London Electric Supply Corporation has, at last, passed the "experimental stage;" that its capital expenditure, now amounting to £821,000, has terminated; and that a profit, if not a dividend, may be earned by December next. The total paid-up capital of the Company is £836,000 in round figures: to pay, say, 5 per cent. on this would require £42,000. The total receipts last year were £24,282, and the total expenses £28,196, so that the Directors and engineers have certainly need of all their patience and ingenuity. There is good reason for attributing the position of this Corporation to sheer bad luck rather than to faulty design. The load was transferred to the Deptford station in October, 1890, and the very next month the fire at the Grosvenor Gallery sub-station compelled the shutting down of the supply for three months, thus losing the winter's work. Starting again with 9,000 lamps in February, 1891, they quickly picked up to 23,000 in May, and by the end of the year had reached 36,000, or about 2,000 less than at the date of the Grosvenor Gallery fire. The next accident, the burning of the mains at Spa-road, shook the faith of their customers, and only 1,000 lamps or so were added during 1892. While the connections during the present year seem to be at the rate of about 22,000 per annum and have reached 57,000, the cutting of prices by the competing companies adds another burden to the difficulties against which this Corporation has been fighting. What mercy they would have shown their rivals had all gone well, and had the huge plant at Deptford been fairly loaded, we need not venture to guess.

Those interested in the latest birth of time, the alternate-current transformer sub-station system of distribution, will do well to take note of the case "Lindsay v. Cowper," which we report in our "Legal Intelligence" this week. If the ticking of a meter and the "hum" of transformers twenty feet below the street are to constitute an actionable nuisance, the alternate current men are evidently not out of the wood yet.

The manifesto, if we may so call it, which we publish this week over the names of Messrs. Crompton, Garcke, and Sydney Morse is a distinct sign that the National Telephone Company's proceedings in regard to electric traction are at last to be placed in their proper light, and that there need be no fear lest judgment should go against the claims of electric traction by default at the forthcoming Parliamentary inquiry. The last paragraph embodies a statement of the case, which has been made over and over again in these columns, namely, that it is a question as to whether the public are to be permitted to enjoy a cheap and efficient mode of traction or are to allow single-wire telephony to be perpetuated. The contention of the National Company, that the insulation of tram-wires is as easy, as cheap, and as imperatively necessary as that of electric light conductors, is ingenious, and likely to have much weight with a non-technical committee. As an answer, it will, however, only be necessary to point to the Folkestone case, where the Company declined to carry out this cheap, easy, and necessary job at its own expense, preferring to pay the promoters' costs, which were decidedly in excess of the Company's estimate for insulating the tram return.

In connection with the controversy which has recently taken place in our columns, and elsewhere, as to the relative claims of the various inventors of non-synchronous alternate-current motors, we have just received two letters which involve two fresh claims of priority. One of these is advanced by the well-known electrician, Herr Jehl, of Brünn, who reminds us of an article appearing in *The Electrician* for October 28, 1887, in which he describes a method of starting motors by producing a rotating magnetic field in a manner very similar to that recently given in the *Elektrotechnische Zeitschrift* in an article written by Herr Arnold of the Oerlikon Works. On referring to this six-year-old article, we find the fact to be as

Digitized by Google

stated by Herr JEHL, but the result is only achieved by means of a complicated commutator and numerous brushes. Moreover, the chief object the inventor had in view was the transformation of direct currents. After all, the production of a rotatory magnetic field is not in any way new, although the recently-acquired habit of referring to such a field by the foreign name of "drehfeld," has made it appear so. Long before 1887, Profs. AYRTON and PERRY devised a motor in which the power applied to the moving part was maintained by means of a rotating field. In this motor the fixed coils were wound continuously in a Gramme ring, and were connected with a commutator in the ordinary manner. A steady current was passed through the ring by means of two brushes pressing on the commutator segments, and revolving over its surface. Some of the recently-devised methods of getting rotating fields involve this plan.

THE other claimant we alluded to is Dr. HANS BEHN-ESCHENBURG, who states that the motor recently described by Mr. BROWN is exactly the same in principle as several motors which have been for some time in use in the Oerlikon Works. After inventing these motors, and, apparently, while preparing a Paper dealing with their theory and historical origin, the learned Doctor seems to have made the unexpected discovery that much of the merit of priority is due to ELIHU THOMSON and TESLA. The disadvantages of the Oerlikon motors are stated to be the excessive current at starting or on light loads and the small range of speed and torque available. With the view of getting rid of these defects Dr. ESCHENBURG has introduced some interesting novelties in the construction of these motors. Briefly stated, the moving and stationary parts are each magnetised by a set of coils joined together in series like a Gramme ring, and connected up in the usual way to the bars of a commutator. The moving part receives current from two fixed brushes rubbing on the commutator. The commutator connected with the fixed coils is also provided with two brushes, whose position is adjustable, connected to a resistance the magnitude of which can be varied. By adjusting the position of the brushes and the magnitude of the subsidiary resistance, it is stated that it is possible to start the motor on full load with a comparatively small current, and also that the speed and torque are adjustable without more sparking occurring at the brushes than is the case with a direct-current dynamo. No data are yet available in confirmation of these statements, nor is any indication given of the magnitude of the power wasted in the subsidiary resistance, or of the size of the motor compared with a direct-current motor of the same output.

THE article on the accuracy of copper voltameters, which we publish this week, calls attention to a matter of no small commercial importance which does not appear to have received the attention it deserves. It has long been well-known that the theoretical quantity of copper is not deposited on electrolysis, and that the weight of metal yielded varies in an irregular fashion both with the current density and with the amount of acid in the solution; but no systematic attempt to explain the discrepancies observed, and to suggest a remedy, appears to have been made before, although those engaged in the recovery of copper by electrolysis were fully aware that they were not obtaining the theoretical yield. Dr. OETTEL has shown the mode in which the difficulties connected with the electro-deposition of copper may be overcome, and when it is taken into consideration that he finds this is effected by the addition of a reducing agent, there can be little doubt that the loss is due to the greater or less quantity of persulphuric acid and persulphate of copper formed in the electrolyte according to the conditions of working. Those who have had experience of working with Daniell's cells are aware that copper is deposited on any speck of carbon which may exist in the porous pots; and, further, that this deposition takes place when the cells are at *rest*. Dr. MARSHALL showed in 1891 (*Chem. Soc. Jour.*, 1891, p. 784) that copper persulphate exists, and that it is a very unstable body, and it appears not improbable that the deposition of copper which takes place during rest after electrolysis is due to the decomposition of this body.

"COOKING by electricity" has been gradually developed after persevering experiment, and has now become well established. Seldom has a useful branch of trade been started under such ridicule. Not the necessary kitchen boiler but the frivolous drawing-room tea-kettle, not the conservatory stove but the perhaps more frivolous curling-tongs, have received attention from clever electricians. There is a good deal more in the design of these appliances than at first sight appears. The selection of the best kind of enamel and a suitable alloy from which to draw the wire, have been carefully studied, and no wonder they are kept secret. Unlike electric lighting, for which wretched wooden lampholders, bad wire, and cheap switches were at first used, while the supply of current was costly, the difficulty in electric cooking has been the high price of the utensils, though the cost of current is small enough. The result, however, is as it was with electric lighting, that electric cooking has been an expensive luxury. With the exception of some figures given by Prof. AYRTON at the Royal Institution in a lecture which, as far as we are aware, has never been printed, no authoritative statement has been published about the cost of current. Mr. DOWSING gives some interesting information in a letter which will be found in our Correspondence columns, and undoubtedly establishes the small cost, not as compared with gas or spirits, but the small absolute cost of electric supply for these purposes. We hope that the price of the apparatus will soon be reduced.

IT has been assumed by theorists who would, probably, be quite incompetent to design an electric kettle or grill that the efficiency of such apparatus is 100 per cent. We have ourselves admitted in some calculations on this subject (*The Electrician*, Vol. XXVIII., p. 478) that the whole of the energy is turned into heat, but it does not follow that the apparatus utilises the whole of it. Careful lagging with asbestos, and the production of the heat at the exact point at which it is required, are necessary, and a reduction in the thermal capacity of the hot plate seems advisable, for though

Digitized by Google

this acts as a kind of fly-wheel, checking the sudden rise of temperature of the resistance wire and afterwards giving out a steady delivery of heat, it is evident from Mr. DOWSING'S figures that the cost of warming up greatly exceeds the expenditure during the process of cooking.

THE breakfast-table egg-boiler is all very well, but unless a chemist's "stink chamber," with its usual powerful ventilating appliances, is provided on the side-board, the grill and frying-pan must be kept in the kitchen, in spite of the ease with which they can be connected to any lampholder. We would, however, suggest that, now we have no dining-room fires, a bottle-warmer to take the chill off the claret would be easy to make and convenient to use. The electric cigar-lighter is, at present, an absurdly clumsy arrangement, with a big handle containing a mercury switch, a box against the wall with a resistance, or an unusually ugly bracket and lamp. Could not a little affair be made about the size of a cigar-cutter, or, perhaps, combined with one, and arranged to cut in in series with the lamps used for lighting the table?

Electric Traction in Toronto.—Over seventy miles of additional electric tram lines are to be laid during the coming summer.

Académie des Sciences.—Prof. Rowland has been elected Correspondent pour la Section de Physique in place of the late M. Soret.

"Practical Physics."—A fourth edition of Glazebrook and Shaw's "Practical Physics" has been issued by Messrs. Longmans, Green, and Co.

Electric Launches.—Four electric launches are to be put on a large lake near Berlin by the Allgemeine Elektrizitäts Gesellschaft, the largest accommodating sixty persons.

Nottingham.—Mr. F. H. Tulloch, an inspector of the Local Government Board, held a local inquiry on Thursday last week with regard to the application of the Corporation for sanction to borrow £45,000 for the purpose of lighting the town by electricity.

"Popular Lectures and Addresses."—A French translation of Lord Kelvin's "Popular Lectures and Addresses" has been published by MM. Gauthier-Villars et Fils. The translator is M. Lugol, who has added notes of his own. M. Brillouin has contributed translations of extracts from recent papers by Lord Kelvin.

The Design and Construction of Dynamo Machines and Transformers.—On Tuesday, May 30th, Mr. Swinburne will deliver the first of a series of lectures on "The Design and Construction of Dynamo Machines and Transformers" to the students of the Electrical Standardising, Testing, and Training Institution.

Royal Society.—A Paper by Dr. Beevor and Prof. Horsley, entitled "A Further Minute Analysis by Electric Stimulation of the so-called Motor Region of the Cortex Cerebri in the Monkey," was down for reading yesterday before the Royal Society.—The late Lord Derby has bequeathed a sum of £2,000 to the Royal Society.

Cable Interruptions and Repairs:—

	Interrupted.	Repaired.
Gibraltar-Tangier	April 29th.	May 16th.
Para-Maranham	March 20th.	—
Paramaribo-Cayenne	April 15th.	—
Santiago de Cuba-Mole St. Nicholas.	April 20th.	—
Asab-Massowah	May 15th.	—

Thunderstorms.—During the week the Thames Valley, the Midlands, and Devonshire have been visited by more or less severe thunderstorms. At Tiverton, The Lodge, the residence of Major Fletcher, was damaged by lightning, which struck a large chimney, passed through the slate roof into a dressing-room, here fused the wire of a picture, followed the course of a wire bell-rope, and entered the wall. From the dressing-room the discharge travelled to the pantry, fusing a gas-pipe, and knocking off and blackening the mortar.

Electric Traction Patents in America.—The two patents recently granted to the assigns of the late Mr. Chas. J. Van Depoele, cover the essential features of the trolley. The patent is assigned to the Thomson-Houston Company. The claims allowed cover, first, the underneath contact made either by a rolling wheel or a sliding spoon contact piece; secondly, the converse of these two cases; and, thirdly, the reversibility of the trolley pole on top of the car, enabling the contact to be made on either side of the trolley, as the case may be.

Interurban Telephony.—Bregenz, on the Lake of Constance, and Feldkirch, on the Swiss frontier, are to be telephonically connected. Extensions of the line will run from Bregenz to St. Gallen, in Switzerland, on the one hand, and to Lindau, in Bavaria, on the other. On the 20th ult. the Vienna-Prague telephone trunk line was opened. The opening of this line places Vienna subscribers in connection with all the Bohemian towns, some twenty in number, connected with Prague. The charge for three minutes' conversation is 1fl. 50kr. (3s.)

"Stabilit."—This is the name given by the Allgemeine Elektricitäts Gesellschaft of Berlin to a new insulating compound, the ingredients of which are, of course, a secret. "Stabilit" has a specific gravity of 1·6, and a specific insulation resistance of 10,000 megohms per cubic centimetre. It is stated to be able to resist acids, damp, high temperatures and high electrical pressures. Its inventors have for some time past used it for armatures, commutators and switch-boards. The substance takes a high polish, and lends itself to all manner of working.

The Westinghouse and General Electric Companies.—The American daily papers to hand contain most sensational accounts of an impending legal fight between the Westinghouse Electric Company and the General Electric Company. It is alleged that prices, specifications and designs have been sold by Westinghouse *employés* to the General Electric Company. A superintendent of the latter Company has already been arrested, as well as several Westinghouse *employés*, and it is stated that warrants are out for the arrest of high officials in the service of the General Electric Company.

The Post Office and Railway Messages.—On the consideration of the London and North-Western Railway Bill, as amended, the following clause has been, on the motion of Mr. A. Morley, added to the Bill:—Nothing in this Act shall be deemed to impose upon the Postmaster-General the obligation of transmitting, under the provisions of "The Telegraph Act, 1868," or any agreement between the Postmaster-General and the Company made in pursuance thereof, any larger number of telegraphic messages of the Company free of charge than he would have been bound to transmit had this Act not become law.

Yarmouth.—A petition, signed by 200 tradesmen and others, was read at the last meeting of the Town Council, asking the Mayor, on behalf of the inhabitants generally, to cause a poll to be taken to ascertain whether it was really the wish of the ratepayers that an electric lighting scheme should be undertaken by the Corporation. The Clerk said the Mayor had no power to order a poll to be taken. As application had been made to the Local Government Board to sanction the borrowing of £15,000 for electric lighting, a public inquiry would be held, of which public notice would be given. Any persons who were opposed to the scheme could attend and state their views,

St. Pancras Street Lighting.—At the meeting of the Vestry, on Wednesday of last week, attention was called to the inconvenience occasioned by the failure in the electric light on the previous Monday night. The arc lamps in Euston-road went out, and the thoroughfare was in darkness for an hour and a-half. Mr. Gibb said, though the failure was a small thing in itself, yet it was most important from the point of view of the ratepayers. He did not think the failure had anything to do with the coals, but was the fault of the stokers in charge. Mr.

Digitized by Google

Edward Cox said that this was the second time that a failure of the kind had happened, and on both occasions it had occurred when the same men were on duty. A full inquiry would be made by the Committee. Mr. McGregor said the supply of current was most irregular. A full inquiry was promised.

The Edison Lamp Patent in France.—The Neuvième Chambre du Tribunal de la Seine has given judgment in an action for infringement brought against M. Khotinsky's French concessionnaire by the Société Générale des Lampes Incandescentes, owning the Edison patents. The Court decided :—(1) That the Edison patents, upon which the plaintiffs rely, are themselves null and void, and cannot, owing to the anticipations investigated by the experts, give the Société Générale des Lampes Incandescentes the right to claim an exclusive property in an electric lamp consisting fundamentally of a carbon filament of high resistance enclosed in an exhausted bulb and connected to platinum conductors traversing the glass of the bulb. (2) That the Khotinsky filament made from a cellulose, amorphous, colloidal paste has, moreover, nothing in common with the Edison filaments made from fibres or fibrous substances. On another issue the Court decided that it was an infringement to make use in new lamps of patented sockets taken from old lamps.

Obituary.—We regret to announce that on May 1st, at Salina Cruz, Mexico, Mr. James Ford Lumsden, son of the Superintendent of the Submarine Department of the General Post Office, was drowned by the upsetting of a boat while landing the shore end of a cable from the ss. "Silvertown." Mr. Lumsden was in his 24th year. He had served on both the engineering and electrical staff of the Silvertown Company, and showed great promise.——We record with regret the death of Mr. E. J. Burt, of fever, on Sunday last, at Sao Thomé, West Coast of Africa, aged 41. The deceased, who was the Superintendent of Sao Thomé Station and latterly acted as Superintendent of the whole of the West African Company's system, joined that Company's service in October, 1885. He had previously seen some thirteen years' foreign service in Central and South America. He was respected alike for his administrative ability and for his natural urbanity, and his premature decease has deprived the Company of an excellent officer. His loss will be keenly felt by a large circle of friends connected with telegraphy in all parts of the world.

Copper.—It would appear that Tasmania may yet be an important producer of copper. Dr. E. D. Peters in his report on the Mount Lyell Company, says that there are several bodies of barren pyrites in the world as large or larger than this one, but its only competitor among the valuable pyrites bodies of the world is the Rio Tinto mine, in Spain, which is three or four times as large as the Mount Lyell mine, but only one-third as rich. He also says that, after making deductions for poor parts of the ore body, there are several million tons of good ore available above the present drainage level of the valley, which can be extracted by simple quarrying and without cost of pumping or hoisting.—Further particulars have been received from the officials of the South-west Africa Company in Damaraland with regard to the recent discovery of copper north of Otavi. They describe it as the finest mineral outcrop they have ever seen.—The copper statistics show an excess of consumption over supply, with the result that on May 15th the visible stock had fallen to 50,289 tons, compared with 52,094 tons at the end of April, and is now smaller than at any time since the operations of the French syndicate.

Electrical Bills in Parliament.—The Unopposed Bill Committee of the House of Commons have passed the Bill confirming Electric Lighting Provisional Orders granted by the Board of Trade to the Vestry of Hammersmith, and the District Boards for Hackney and Poplar. The examiners of the House of Commons have ordered to be reported for second reading the Bill confirming the Electric Lighting Provisional Orders granted to the Bridgend Local Board and the Taunton Town Council. On Monday the Bill for amending the City of London Electric Lighting Bill was read a first time, and referred to the examiners of petitions for private Bills. On Tuesday, the Barry Railway Bill was read a third time. The Electric Lighting Provisional Order (No. 1) Bill was referred to a Select Committee of the House of Commons, of which Mr. A. De Tatton Egerton was chairman, and which met on Monday. The Bill was opposed by the Corporation of Glasgow. In the House of Lords on Monday the Electric Lighting Provisional Orders (No. 2) Bill was read a third time and passed. On Friday of last week the Royal Assent was given to the Kensington and Knightsbridge Electric Lighting Company's Bill ; and the Hampstead, St. Pancras and Charing Cross Railway Bill, the Brighton and Rottingdean Seashore Electric Railway Bill, were read a second time.

M. Dolivo-Dobrowolsky and the Brown Motor.—The *Elektrotechnische Zeitschrift* for March 31st contains a lively impeachment of Mr. Brown and his motor, from the pen of M. Dobrowolsky. The latter asserts that he built a practical three-phase motor at the works of the Allgemeine Elektrizitäts-Gesellschaft in 1889, and that some data were sent to the Oerlikon Company, and the 3-4 H.P. motor was shown to Messrs. Huber and Brown in 1890, who thought so well of it that they entered into an agreement to manufacture under licence, and to work on improvements in concert with the Gesellschaft. Before this, no alternate-current motor had worked at Oerlikon. This, says the author, disposes of Brown's claims to priority. Under the agreement, M. Dobrowolsky gave, both by letter and word of mouth, details of the machines to Mr. Brown, and he gives long quotations from his letters. The armature of Brown's motor, says the author, is entirely taken from his; and he shows that his armature has been improved so that it runs as much as 50 ∿, whereas he quotes Mr. Swinburne to show that Brown's will not run over 25 ∿. Winding through holes in the iron was tried by M. Dobrowolsky in the machine shown to Mr. Brown, and has been done away with by using notched armatures; and those constructed by Mr. Brown under M. Dobrowolsky's instructions have been much improved by his successor at Oerlikon. The connection of Mr. Brown with the development of the alternate-current motor is, says the author ironically, perfectly clear. After criticising the details of the "new" motor, the author gives some details of the three-phase motors of the Allgemeine Elektrizitäts Gesellschaft, running at 50 ∿, and challenges Mr. Brown to produce similar figures for his motors, and to run his motor against that of M. Dobrowolsky.

The Hummel-Schuckert Meter.—In a recent number of *L'Electricien*, M. E. Meylan describes the Hummel-Schuckert meter, which has come into tolerably wide use in Germany and Switzerland, and also gives the results of some tests. This meter may be briefly designated as a German variety of the Elihu Thomson motor meter. The field-magnets are excited by the series coil. The armature is in shunt, and in series with it there are the coil of the retarding electromagnet and the coil acting on the armature and intended to compensate for friction. The armature is merely a spheroidal bundle of wires. The damping device is extremely light. The commutator of the motor is formed by seven silver segments, the brushes each consisting of a strip of silver bent into a U, the edges bearing on the commutator. According to M. Meylan, the performance of the Hummel meter compares badly with that of Elihu Thomson. A 10-ampere meter was taken, and the volts were kept 98·5, whilst the current was varied from 0·2 to 8·15 amperes, then the volts were kept at 100 and the current varied from 0·4 to 13·6 amperes; finally the current was kept at 2 amperes, and the volts varied from 111 to 95. The results showed that the compensating coil was too powerful, and the core of the retarding electromagnet insufficiently saturated. M. Meylan points out that the great thing in these motor meters is to obtain relatively powerful torques in order to reduce the influence of friction to a negligible quantity. The torque of the 10-ampere Hummel meter at full load is 10·4 gramme-centimetres, that of an Elihu Thomson 15-ampere meter being 20 gramme-centimetres, the moving parts of the latter being, however, somewhat heavier. M. Meylan then shows that the horizontal component of the earth's magnetism, not to mention externally-placed magnets, may have a marked effect on the readings, owing to the comparatively weak field of 120 C.G.S. units at full load. The horizontal component of the earth equals 0·2, so that it may cause a variation of 0·4/120, or 0 3 per cent. at full load, or 3 per cent. at one-tenth load.

THE ACCURACY OF THE COPPER VOLTAMETER.

BY BERTRAM BLOUNT, F.I.C., F.C.S.

The fact upon which the use of an ordinary voltameter is based, namely, that a given current performs a definite and constant amount of chemical work, is not to be gainsaid; but the common deduction, therefrom, that if two strips of copper are immersed in a solution of copper sulphate and the gain of the cathode determined after the passage of a current an accurate measure of that current is obtained, cannot be accepted without reservation. At a date not very distant, a nice, neat, simple equation was thought to express with accuracy any typical straightforward reaction, and anything simpler or more straightforward than the electrolytic decomposition of copper sulphate it was difficult to conceive. But chemists, who are a prying, unsatisfied race, have disturbed this comfortable belief, thereby greatly distressing many worthy makers of books and the honourable company of examiners and examinees, and have searched for, and in too many instances found, secondary reactions accompanying those which are more obvious, with the result that many a symmetrical expression has become sadly lopsided. It is in some sense consoling that the destruction of a favourite superstition has, in this case, been attended with practical advantage, and though the decomposition of copper sulphate may have been found to be irregular to the verge of impropriety, a knowledge of its vagaries may be applied to the attainment of greater accuracy in results arrived at by its means. The subject has attracted some attention on the Continent, and a series of experiments by Dr. Oettel has recently been published in the *Chemiker Zeitung*, from which a good deal of interesting information may be gleaned.

In the first place, if the decomposition of copper sulphate were perfectly regular it would obviously be a matter of indifference whether copper or platinum electrodes were used, for the only immediate effect of the substitution of the latter for the former would be an extra drop of voltage due to the fact that copper was not being merely transferred from the anode to the cathode, but that it was being actually reduced from its sulphate. In an apparatus containing platinum electrodes, however, and with a current density of 0·13 ampere per square decimetre (about 0·0084 amperes per square inch) of the cathode surface, the amount of copper deposited ranged from 73·9 to 89·2 per cent. of that thrown down in a voltameter with copper electrodes included in the same circuit. No evolution of hydrogen appeared to take place at the cathode, so that it was not at first clear what work other than the deposition of copper had been done by the current. As both the copper sulphate and sulphuric acid were chemically pure, no explanation was forthcoming based upon any irregularity in the composition of the electrolyte, and the cause of the low results was sought in some change at the anode, by which less than the calculated amount of oxygen appeared there as gas. Only three bodies seemed likely to be formed, namely, ozone, hydrogen peroxide and persulphuric acid. The first was put out of court by the fact that the oxygen was free from the very powerful and characteristic smell of its allotropic modification. Of the two remaining substances, persulphuric acid, HSO_4, is the more likely to have been produced, as recent researches have shown that this acid and its salts are quite readily prepared by means of electrolysis, but it is to be regretted that no attempt was made to settle the question in a satisfactory manner. The reactions of hydrogen peroxide with chromic acid and titanic acid should have sufficed to dispose of the doubt as to its presence, for those which were actually tried, such as the liberation of iodine from potassium iodide, are given by hydrogen peroxide as well as by persulphuric acid. One of Dr. Oettel's experiments, indeed, points plainly to the presence of hydrogen peroxide. He found that the liquid at the anode decolourised a solution of potassium permanganate, a reaction by which Dr. Marshall (*Chem. Soc. Jour.*, 1891, p. 774) distinguishes hydrogen peroxide from the persulphates. Whichever substance was formed, however, its effect was the same. After its formation at the anode, it diffused through the liquid to the cathode and there was reduced instead of copper, the net result being extra work in the cell, which finally appeared as heat. Persulphuric acid being still a comparative novelty, and being, moreover, by no means particularly stable, would certainly be overlooked by many, and it it is just as well to call attention to its existence and the ease with which it is formed when sulphuric acid or a sulphate is electrolysed.

The influence of current density is not easy to reduce to a definite rule, but it seems from such facts as have been collected, that the use of a small anode, as compared with the cathode, favours the formation of persulphuric acid, and therefore a loss of copper. This is quite in accord with the well-known effect of a small anode on the production of ozone by the electrolysis of dilute sulphuric acid, a wire being found preferable to a plate, and the mere end of a wire better still. Raising the content of acid in the electrolyte also decreases the amount of copper deposited, both from the enhanced production of peroxidised products at the anode, and also from the action of the acid on the copper at the cathode tending to redissolve it. The material of which the anode is made is not without influence on the results. Lead, when used instead of platinum, becomes coated with a film of lead peroxide and is then scarcely attacked, while the amount of copper deposited increases to 97-98 per cent. of that thrown down in a copper voltameter in the same circuit. This fact again goes to show that hydrogen peroxide is one, at least, of the products at the anode, for it is decomposed by lead peroxide, with the formation, in the presence of sulphuric acid, of lead sulphate and oxygen, and thus less loss from the reduction of a peroxodised body at the cathode takes place, while the formation of lead sulphate involves a slight increase in the voltage of the current passing through the cell, the energy requisite being furnished by the heat of formation of lead sulphate. A persulphate, on the other hand, although readily decomposed by treatment with a salt of lead on account of the unstable character of lead persulphate, does not react with lead peroxide in the same manner as does hydrogen peroxide. These considerations lend considerable weight to the belief that hydrogen peroxide, as well as persulphuric acid, is among the products at the anode, in which case the addition of a trace of manganese sulphate added to the electrolyte should have the same effect as the use of a lead anode, for the resulting manganese dioxide would also decompose hydrogen peroxide. The suppression of the peroxidised body at the anodecan be effected by other means than the use of a metallic peroxide at the anode. Thus, when formic acid, which is readily oxidisable, is added to the contents of the decomposing cell, the yield of copper rises to 98·7-99·6 per cent. of the theoretical amount. Alcohol is even more active, and the copper separated is as much as 99·5 to 99·9 per cent. of the ideal quantity. That the reaction takes place on the lines already indicated is proved by the formation of a considerable quantity of aldehyde, the lowest oxidation product of alcohol, at the anode. Aldehyde is not readily reduced to alcohol, so that no loss due to the reverse reaction takes place at the cathode. The energy evolved in the oxidation of the alcohol probably appears in the form of heat, there being no evidence that it contributes to the electrical energy of the system.

These observations rather cast doubt on the accuracy of the copper voltameter, in which both electrodes are of copper, at least when used with an acid electrolyte. This is a matter of practical importance, as the copper voltameter is constantly used in preference to the silver form of the instrument, not only because of the difference in the price of the two metals, but also on account of the compact condition in which the copper separates, while the silver, on the other hand, is loose and crystalline—a drawback in lengthy runs. The usual prescriptions for setting up a voltameter to give reliable results insist on the necessity of using a neutral solution of copper sulphate in spite of the high resistance thus caused, a resistance that is lowered one-half by the addition of a moderate quantity of sulphuric acid. The observation recorded above, that the addition of alcohol prevents the tendency to low results in a voltameter having an insoluble anode, suggests the possibility of avoiding the loss generally supposed to be incurred by the addition of acid, by the same means. The upshot of a long series of experiments by Dr. Oettel with varying current and current density may be stated as follows:—An acid solution of copper sulphate containing alcohol

Digitized by Google

gives results which agree with those of a standard copper voltameter and of the silver voltameter. With a current density below 0·3 ampere per square decimetre (0·0193 amperes per square inch), the ordinary copper voltameter, working with a neutral solution of copper sulphate, gives false results, the weight being unduly increased by the presence of imperfectly reduced copper in the form of cuprous oxide in the deposit. This does not take place with an acid solution containing alcohol.

Finally, Dr. Oettel gives the proportions which he has found most effective for setting up a voltameter free from the objections that can be urged against the ordinary form. The electrolyte consists of a solution of 15 grms. of copper sulphate, 5 grms. of sulphuric acid, and 5 grms. of alcohol in 100 grms. of water. It can be used with a current density ranging from 0·06 to 1·5 ampere per square decimetre (0·0039 to 0·97 amperes per square inch) of cathode surface, and has a resistance half that of a corresponding instrument filled with neutral solution of copper sulphate.

In closing this appreciation of an admirable piece of work, I cannot refrain from recording a few suggestions to which it has given rise. In the first place, the study of the precise nature of the products at the anode would, in my opinion, lead to the detection of hydrogen peroxide as well as of persulphuric acid. Next, there is not only a probability of the presence of oxygen in the copper deposited by a current of low density, but also a prospect, in the reverse case, of the separation of hydrogen at the cathode and its occlusion by the copper. The tendency of copper to associate itself with hydrogen is well marked, even when reduced by dry methods, and the existence of hydrogen in metals obtained by the electrolysis of aqueous solutions of their salts, generally recognised. Finally, as the re-solution of copper from the cathode cannot be effected by the action of dilute sulphuric acid in the absence of oxygen, voltameters of precision should preferably be so arranged that the atmosphere above the electrolyte could be an inert gas like nitrogen. By paying regard to such precautions a substantial advance in accuracy would be gained.

ON THE PREVENTION AND CONTROL OF SPARKING; CONTINUOUS-CURRENT DYNAMOS WITHOUT WINDING ON THE FIELD-MAGNETS, AND CONSTANT-PRESSURE DYNAMOS WITHOUT SERIES WINDING.*

BY W. B. SAYERS.

The object of this Paper is chiefly to lay before the Institution certain means for bringing under independent control the commutation of ring and drum armatures for continuous currents. The limits dependent on considerations of sparking at the brushes being thereby done away with, a new field of design is opened up. Mr. Swinburne and Mr. Esson—the former in his Paper read before this Institution in 1890, and the latter in his Papers in 1890 and 1891—both give expressions for the maximum load which can be carried without sparking; these expressions are in terms of the ampere-turns upon the armature, the length of the air space, the angle subtended by the polar surfaces of the field magnets, and the forward induction. Thus, it is recognised that in ordinary ring and drum-armature machines the consideration of sparking fixes, or at least limits in one direction, some of the most important elements in the design of the machine, and is not separately controllable. A practical result from this is that the lightening of machines by putting the conductors in tunnels, reducing the air space to a mere clearance—which has been proposed from time to time, notably by Mr. Swinburne, and which is the condition in which minimum exciting force is required, and, consequently, the condition of minimum weight of magnets—has not been hitherto practicable. The conditions of sparkless collection, when no special means are employed for bringing about the reversal of the sections as they pass the diameter of commutation, are now well understood; but as I have found it somewhat difficult to describe the action of the devices which I wish more particularly to bring under consideration, I have prepared four diagrams which I think represent the action fairly well, and which will at least be useful as a stepping-stone towards that which I wish to describe later on.

* Paper read before the Institution of Electrical Engineers, May 11th.

In diagrams 1 and 8 I have ventured to distinguish the currents flowing from the two halves of the armatures by red and blue colouring* beside the wires in which they are flowing. This is merely to enable me to refer briefly to the two halves of the current, and to clearly distinguish them in the diagrams.

Diagrams 1 to 4 represent part of an ordinary ring-armature machine spread out flat. Suppose, as is the case usually, the brush makes contact over an angular breadth equal to that of one section of the commutator, or a little more; then the current reaches the brush alternately through one commutator bar, and through two. Figs. 1 and 3 represent diagramatically these two conditions. In Fig. 1 the commutator bar C is represented centrally under the

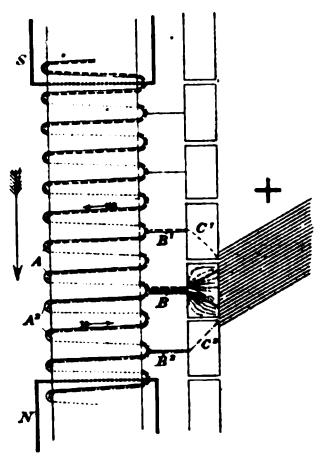

Fig. 1.

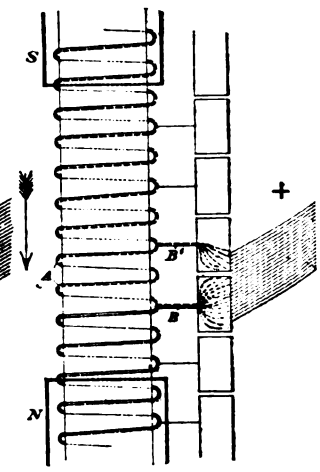

Fig 2.

brush. In this position the currents flowing from the two halves of the armature unite in the commutator connection B, and flow thence through the commutator bar to the brush. As the armature moves onward in the direction indicated by the arrow, the armature coil A is seen to be short-circuited under the brush. The current flowing in it at the moment when it becomes short-circuited would be counter clock-wise, looking from the lower end, but the coil, from its position, is beginning to cut lines of force in a sense tending to induce a clock-wise current. The counter clock-wise current,

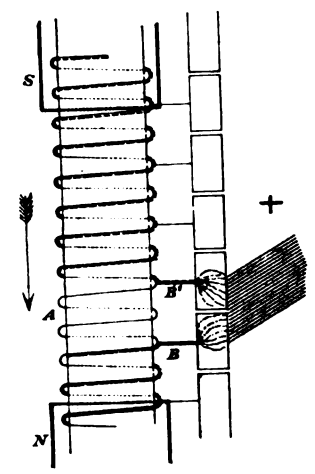

Fig. 3.

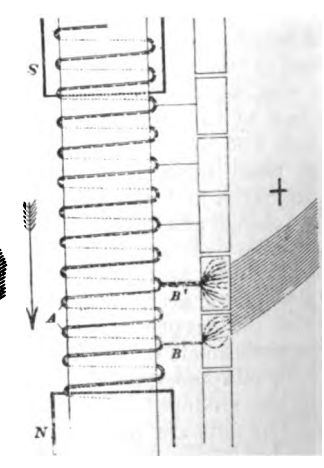

Fig. 4.

therefore, falls, and at the same time a current rises in B^1, such that the current in B, *plus* the current in A, equals at any moment the half-armature current. Fig. 2 represents the position when the red half is equally divided between B and B^1, B carrying in addition the whole of the blue half. The next stage is shown in Fig. 3, when the current in the armature coil A is passing through zero value; at this instant the blue half of current flows to the brush by B alone, and the red half by B^1 alone. A clock-wise current now commences to rise in A, the current in B falling correspondingly. Fig. 4 shows the position when the blue half is equally divided between B and B^1, while B^1 carries in addition the

* In the blocks — — — stands for red colouring, and —·—·— stands for blue colouring.

Digitized by Google

whole of the red half. As the armature still moves on, the position shown in Fig. 1 is again reached, the current in A having risen, under the influence of the induction, to the value of half the armature current. At the instant when this is so, the current in B^2, Fig. 1 (which we now look upon as B moved through the angular distance of one section), is necessarily zero, and if the tip of the brush breaks connection with the commutator at this instant the break will be sparkless.

Several devices have from time to time been proposed for controlling sparking at the brushes of dynamo machine—notably the use of reversing pole-pieces. Mr. Hookham, of Birmingham, told me—I think in 1889—that he had succeeded in obviating the necessity of moving the brushes for varying loads by their means. Mr. Swinburne has also advocated the use of reversing pole-pieces; and Mr. Edison has from time to time since 1883 patented various arrangements with the object of introducing a counter electromotive force into the short-circuited coil, with the object of avoiding sparking and the necessity for moving the brushes with varying loads.

Still, there would appear to be in the minds of some a vague idea that sparking is due generally to an abnormal current being generated in the coil which is short-circuited under the brush. That is far from being true as a general rule, as appears from the actions I have described. An excessive current can only be reached in the short-circuited coil after the requisite reversal has taken place. Take Fig. I. If the brush does not break at the instant here depicted, the current in the armature coil A^2 will rise above the value of half-armature current, a back

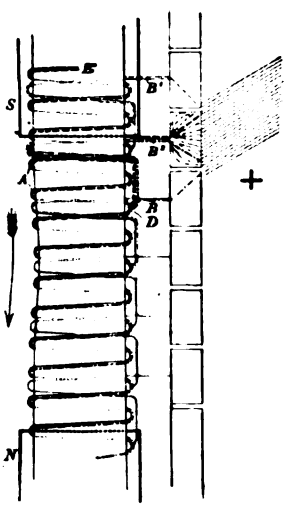

Fig. 5.

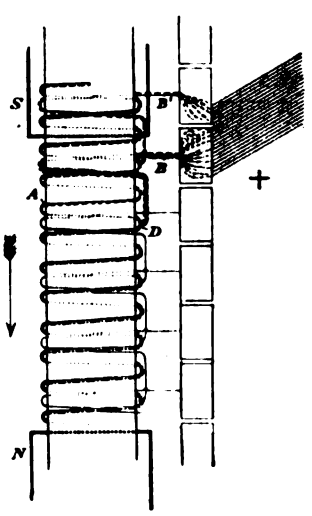

Fig. 6.

current being started in B^2 which flows round through A^2 and B to the brush, and may be considered as superimposed upon the half-armature current in A^2 and B; when the break occurs there will, therefore, be a spark, which, it may be noted, will tend to maintain itself as an arc across the insulation between C and C^2. This excess current in A^2 and B, then, only occurs after the reversal of the section has been duly accomplished—that is, when the reversing of the section has been carried too far. Now, moving the brushes back so that the coil is short-circuited in a slightly weaker field would at once correct this fault. We must, therefore, conclude that if with a given load there is no sparkless position for the brushes of a machine, it is because the coil which has been short-circuited under the brush comes mechanically into the circuit with too little or no current in it, or, in a very bad case, even with the current still in the wrong direction; in other words, the reversal has only been partially effected, or not effected at all, by the inductive action of the field. If in an ordinary machine (speaking of generators) the brushes are shifted backwards so that the armature coils are short-circuited while cutting lines of force of such direction as not to tend to reverse the current in them at all, but rather to increase it, the reversal is only accomplished by the mechanical make-and-break action of the brushes and commutator sections, and is, consequently, accompanied with violent sparking. I think it is abundantly clear, then, that excess of current in the coil which is commutated is never, in practical work, the cause of sparking, but that, on the other hand, sparking which cannot be got rid of by shifting the brushes forward is due to the current of the coil being too small when the break occurs between the commutator section and the brush.

It is still the practice with some makers to use driving-pins at intervals, causing a greater angular space between some of the armature sections than the normal, and the consequence is that the brushes cannot be in the correct position for all the armature coils at the same time. Such machines will invariably be found to be marked at the commutator in a manner regularly increasing and decreasing in relation to the position of the driving-pins: *the marking will be more or less distinct according to the nearness to the same position in which the brushes are set from time to time for the same loads;* because, if in such machines the brush is shifted through a small angle, the sparking is transferred from some sections to others, so that if the brushes are moved about sufficiently the sections will all get marked alike. When the pins are necessary there seems to me to be a very simple remedy for the defect under consideration. I suggested this remedy to Mr. Crompton about 18 months ago, but I no not know whether he has made any experiments with it. The remedy is to make the divisions in the commutator to correspond with the divisions of the armature sections. Thus, in the position corresponding to the position of a driving-pin, there would be a commutator bar having an angular width equal to the normal width of a section, *plus* the angular width occupied by the driving-pin. For good appearance the width of pin might be equal to the angular width of the commutator section, and a dummy section connected to one of its neighbours put in the commutator at the position corresponding to the position of the driving-pin.

Before describing the special means by which I secure the sparkless reversal of the section under the brush at any desired place between the horns of the pole-pieces, I may briefly state the characteristic features of the new machines which the use of the

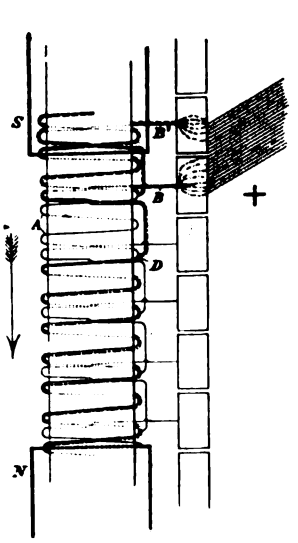

Fig. 7.

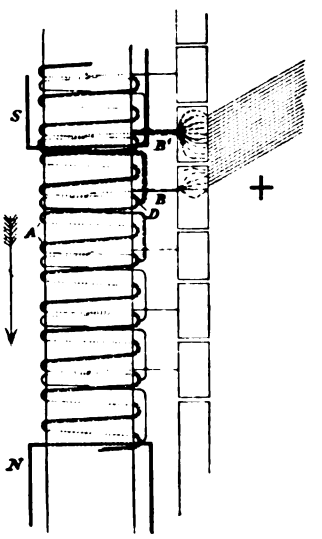

Fig. 8.

devices referred to has enabled me to design. These are as follows:—The air space is a mere clearance—1 millimetre. The reversal of the sections is effected by inductors, or coils, which I have called "commutator coils," independent of the main winding; these commutator coils are so arranged as to be acted on by the pole-tip which is strengthened by the armature current, and the brushes of the machines when run as generators are set with a backward lead instead of a forward one. The commutator coils enabling me to reverse the armature sections just after they have emerged from under the strengthened pole, the result is that what have hitherto been called back turns of the armature winding become forward turns, and the effect of the cross induction is to increase the reversing field instead of to diminish it and the manner they operate in producing it.

The machine illustrated in diagram No. 9 has all of these features. It is self-exciting by means of the armature winding only—that is, it generates a current—behaving like a series machine, of course—without any winding at all upon the magnets, which may, therefore, more properly be called keepers; and it runs absolutely without spark at the brushes.

Before further describing this particular machine, I will describe as clearly as I can the means which I adopt for obtaining these results. Figs. 5 to 8 represent diagrammatically a ring armature machine wound with "commutator coils" for causing the reversal of the armature sections close against the horn, which is strengthened by the armature reaction. The commutator coils consist of coils wound around the armature core, and each connected at one end to the main winding at points between the sections, and at the other end to the commutator segments. There are thus as many commutor coils as there are sections in the armature. The commutator coils are placed at an angular distance from the sections of

Digitized by Google

the winding between which they are connected, being from one to two sections nearer the pole horn, which is strengthened by the armature current. The direction of winding of the commutator coils relatively to the main winding is such that if the winding is followed around the core from a point in the main winding under the "flux" horn—which I have ventured to name the horn which is strengthened by the armature current—in the direction which leads out from under the tip of the horn to a point where a commutator coil branches off, and the commutator coil is then followed, the wire leading to, and forming, the commutator coil doubles back under the flux horn, and is then wound around the core in the same direction as that followed when tracing the main winding. This will be seen clearly on referring to Fig. 5. Starting from the point E, and following the main winding down to the point D, then passing up commutator coil B, it will be seen to pass around the core in the same direction as the main winding. Figs. 5, 6, 7, and 8 represent four stages in the commutation of an armature by means of my commutator coils, corresponding to the four stages represented in respect of ordinary winding in Figs. 1, 2, 3, and 4.

In the following description it will be seen that the actions depend essentially upon the difference of pressure induced in the two or more commutator coils concerned at any time, and it follows that the angular distance between the coils must be considerably greater than the length of the air space, otherwise the difference between the E.M.F. generated in the two bars may be insufficient. This necessity, of course, fits admirably with the conditions in short air-space machines. I have, indeed, made no experiments up to the present with the device on smooth-core armatures, but when used on such machines I think it would be necessary to *reduce* the number of sections in the armature to less than the usual practice, so as to get a sufficient distance between the two commutator coils or bars to produce the required preponderance of pressure in one of the two or more segments under the brush.

Fig. 5 illustrates the approximate conditions when one commutator plate is central under the brush. The red half of the armature current meets the blue half at the point D, whence the whole current passes by the commutator coil B to the brush; and it will be noted that as the coil B is just under the tip of the pole horn, the E.M.F. due to one turn is generated in it, and is added to that generated in the main winding. This being the case at the other brush also, the effect of the commutator coils in increasing the E.M.F. is equal to that produced by four of the main conductors on the periphery of the armature. Fig. 6 represents the armature a quarter section further on than Fig. 5. The commutator coil B having moved away from the pole-tip, and consequently into a weaker field, has less E.M.F. generated in it; there is also a fall of potential throughout its length due to the resistance of the conductor. The commutator coil B^1, however, which is now in contact with the brush, is still under the pole, and B and B^1 are united at their inner ends by the main winding, section A. Now the main winding, section A, although yet a considerable distance from the neutral zone, is cutting few lines of force compared with a coil under the flux horn. Under these conditions, then, the current which was flowing in B is transferred to B^1, under the action of the resultant E.M.F. in the circuit composed of armature coil A and commutator coils B and B^1 completed by the brush.

Fig. 6 shows the instantaneous condition a quarter-section further on than that shown in Fig. 5, half the red half of armature current flowing through B^1, the other half flowing through the armature coil A and joining the blue half at D, and thence through B to the commutator. Fig. 7 shows the point half a section from the starting point depicted in Fig. 5, where the current in the armature, section A, is at zero value, the red half of armature current flowing out by B^1 and the blue half by B.

Fig. 8 shows a point three-quarters of a section from the starting position, when half the blue half is still flowing to the brush *via* B, while the other half has commenced to flow around A (thus starting the current in the required direction in A); arriving at the point D, it joins the red half and flows through B^1 to the brush. Fig. 5 may be regarded as the next stage, the armature having moved through an angular distance equal to one section; the current in B^2 (which we regard as B moved one section on) is almost extinct; A is carrying nearly the normal = half armature current, and by the time the commutator segment breaks with the tip of the brush the current flowing from it will be zero, and the break consequently sparkless.

Proceeding now to consider practical applications of my device, Fig. 9 represents diagrammatically the first machine made self-exciting by means of the armature winding alone. The machine

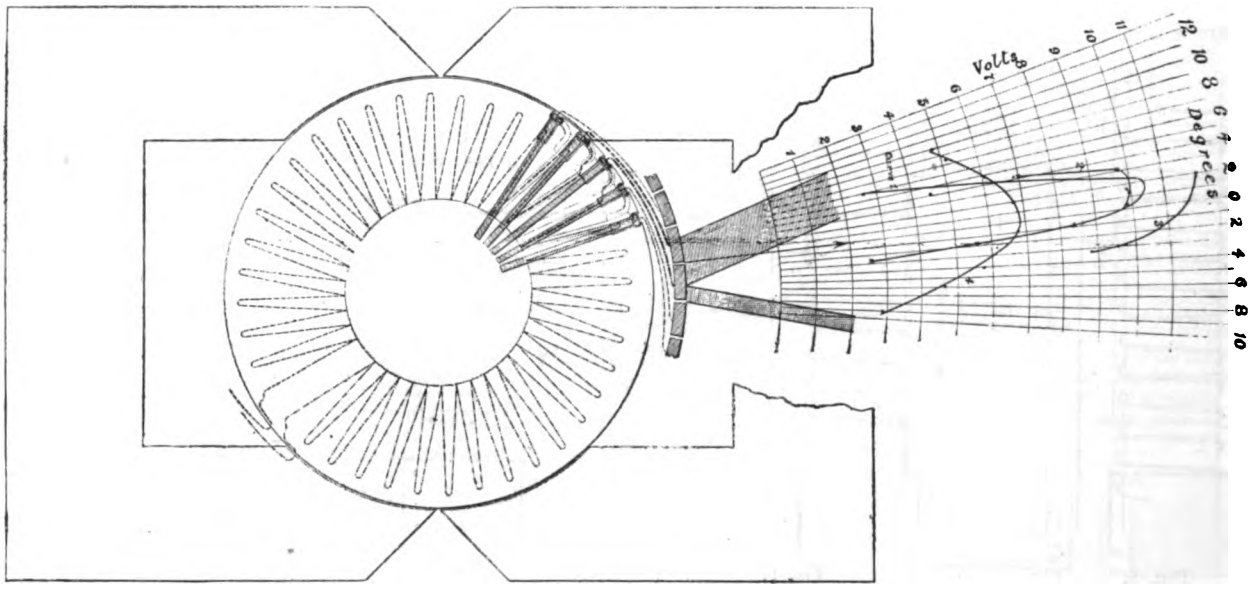

FIG. 9.—Diagrammatic Representation of Dynamo without Winding on Magnets.

is now running at the Bradford Station Hotel, Midland Railway, as a regulator. It is coupled direct to a shunt motor, and driven at constant speed. The main current to the hotel is passed through the armature, causing an inductional proportional to itself, and thus raising the pressure in proportion to the current flowing, and compensating for the drop in the leads, just as a series machine would do under the same conditions.

Particulars and dimensions of the machine are as follows:—

Armature—ring form.	
Diameter, external	9⅜in.
,, internal	4¼ ,,
Length	9 ,,

The periphery has 40 slots cut into it in which the conductors are placed. The slots are ⅜in. deep, ¼in. wide, and each has two grooves cut in it opposite to each other near the top. The main winding conductor is of copper strip 0·15 × 0·5in., and occupies the space in the slot below the grooves. The commutator coils or bars are of copper 0·1in. × 0·3in., with rounded edges, insulated D.C.C., then double-lap tape. They are slid into the slot from one end, their edges fitting into the two grooves. Thus they serve to hold the conductors in position, and so obviate the necessity for binding. The air space is 1 millimetre.

The keepers (they really are not field-magnets) are of double L shape, and made up of charcoal iron plates to prevent heating from the variation of the flux over the polar surface caused by the slots in the armature. The keepers are separated in the centre in order to reduce the cross induction, which is, of course, very considerable. I have had in mind trying Prof. S. P. Thompson's suggestion of

Digitized by Google

making the keepers (F.M.'s) up of separate plates, with the object of reducing cross-induction. In subsequent machines the necessity for laminating the polar surfaces has been obviated by putting the conductors into tunnels, and only running a saw-drift through the crown of the tunnel to break the iron circuit and reduce the self-induction of the section; the well-known device of winding over with charcoal iron wire has also been used.

On testing the machine illustrated in Fig. 9, it was found, as I expected, to be self-exciting, and it will carry a current of 400 amperes at 14 volts running at 900 revolutions per minute. It is capable of running with this current absolutely without spark at the brushes. There is hardly any external field—sufficient, of course, to move a compass, but hardly enough to feel with a piece of iron—except between the two keepers in the space marked F, where there was considerable field, due, of course, to cross-induction.

According to Mr. Esson's formula, the output should be $(20{\cdot}5)^2 \times 22{\cdot}5 \times 15 \times 0{\cdot}048 = 7{,}000$ watts. The comparatively small output obtained—5,600 watts—is accounted for by the fact that for the purpose for which it was designed (to act as a regulator) it was necessary to keep the induction density in the iron below 10,000 in order that the E.M.F. should be, as nearly as possible, proportional to the current.

Fig. 10 is the characteristic curve of the machine—the horizontal distances representing the current, the vertical distances the volts.

The most remarkable feature observed about the machine when self-exciting is its extreme sensitiveness with regard to the position of the brushes, a very small movement causing a great variation in the volts. Moreover, it will not excite at all unless the brushes are within a certain arc of about 9deg., the position of this arc corresponding with the position in which the hindermost commutator bar under the brush is under the pole-tip, and the foremost one has passed out from under it.

The curves to the right of the brush in Fig. 9 represent the volts observed with the brushes in various positions. The pointer drawn through the brush indicates the point in the curve corresponding with the brushes in the position shown. Thus, if the brush and pointer were shifted in either direction, the pointer would indicate the volts corresponding with the position of the brush.

Curve No. 1 is plotted from results obtained when the machine was running at a speed of 850 revolutions per minute, and an external resistance in circuit of about 0·03 ohm, the maximum current reached being about 340 amperes. For curve 2 the speed was 1,000 revolutions per minute; external resistance, 0·038 ohm; and maximum current, 291 amperes. Curve 3 shows the effect of one turn of series winding around each keeper, with speed 1.000; external resistance, 0·0455 ohm; current, 202-265 amperes. Curve 4 shows the effect of moving the brushes when a constant current is passed the through armature: speed, 1,000; current, 200 amperes. These curves are plotted from the tables I., II., III., IV., given on next page.

It will at once be obvious to all that a shunt machine with armature on my principle may be made to keep pressure constant with varying current, part of the armature winding performing the function hitherto performed by the use of series coils on the magnets. As would be expected, the armature coils so used are several times more effective, turn for turn, than an equal number of series coils upon the magnet. First, they count double, because they would exist as *back* turns if the machines were running with a forward lead; and, second, because, whereas in the latter case the effect of the series coils—or, rather, of the remainder of them after subtracting the number of the back turns—depends upon the permeability of the field-magnets and armature, and all magetic leakage is, of course, ineffective, the action of the forward turns on the armature when running with a backward lead, though depending on permeability of the armature core and magnets, is wholly effective, even the leakage (if we so call the lines which do not pass around the magnet cores) being necessarily cut by the conductors on the armature.

Particulars of such a machine are as follows:—

Particulars of 9-unit Shunt-wound Dynamo; 100 Volts, at 920 Revolutions per Minute.

Armature—

Diameter at bottom of slots, $6\frac{7}{8}$in.
Diameter of hole in centre of discs, 2in.
Diameter over all, 9in.
Length of iron core, 10in.
Dimensions of slots, $1\frac{1}{16}$in. deep by $\frac{1}{4}$in. wide.
Number of slots, 40.
Total turns of main conductor on armature, 80.
Turns per section of armature, 2.

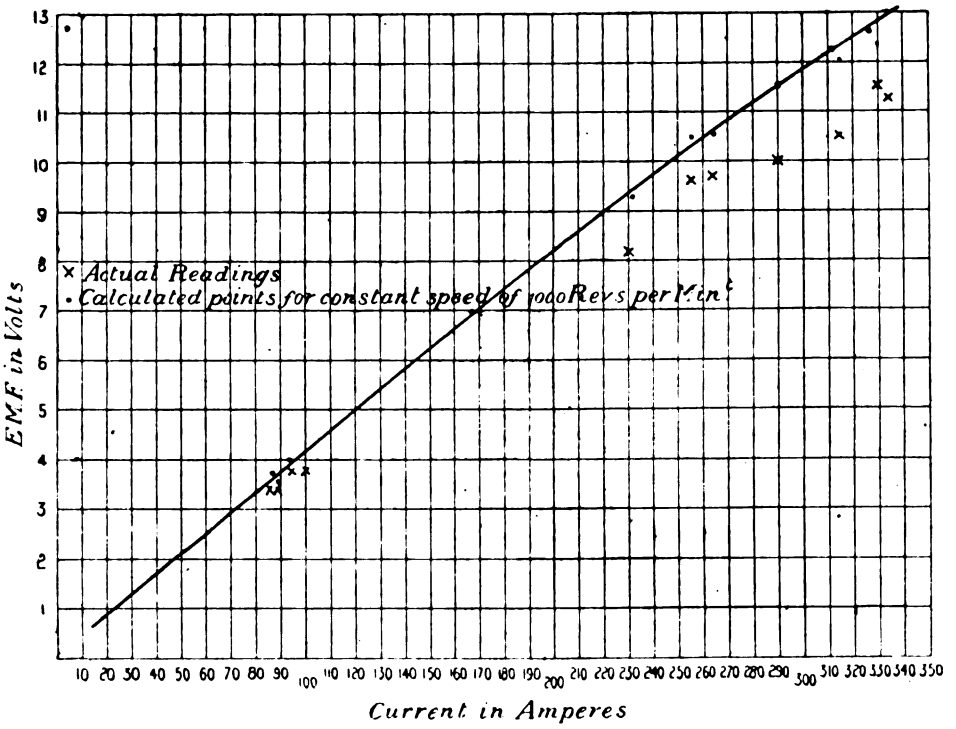

Fig. 10.—Characteristic of Self-exciting Dynamo without Winding on Magnets.

Commutator Coils—

Turns to each section of armature, 1.
Sectional area of main armature conductor, $0{\cdot}180 \times 0{\cdot}160 = 0{\cdot}0288$ square inch.
Sectional area of commutator coils, $0{\cdot}180 \times 0{\cdot}08 = 0{\cdot}0144$ square inch.
Resistance of main conductor between points of connection to commutator coils at T. = 100°F., 0·025 ohm.
Resistance of two commutator coils in series, being the maximum resistance added by these coils to armature, at T. = 100°F. = 0·005 ohm.
Total resistance of armature, 0·03 ohm.

Weight of main armature conductor	35·4lb.
,, of commutator coils	8·8lb.
Total weight of armature conductor.....	44·2lb.

Commutator coils one section in rear when running as generator of armature sections to which they are connected.

Field Magnets.—

Cores of scrap iron, 6in. thick by 10in. broad. Cast 3in. into sole plate at lower ends. Sole plate, therefore, acts as yoke, and has approximately double the sectional area of cores.

Digitized by Google

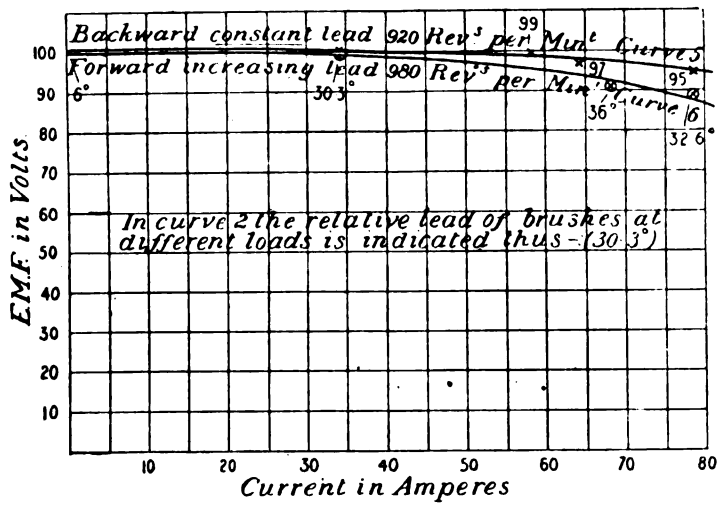
Bore of pole-pieces, $9\frac{7}{16}$in.
Angle subtended by polar face, 130deg.
Length of wound portion of magnet cores, 8in.
Winding, 120lb. No. 18 S.W.G. (0·048in. diameter).
Resistance, 70 ohms.
Total turns, about 5,120.
Ampere-turns in shunt winding, 7,300.
Current through shunt coils, 1·43 amperes.
From the foregoing we get the following in C.G.S. units :—

Armature—
Effective area of core, allowing for 5 per cent. occupied by paper, 297 sq. cms.
Total induction through armature core, 4,000,000.
Density, I = 13,400.

Field Magnets—
Total induction through magnets, assuming leakage coefficient of 1·2 = 4,800,000.
Density, wrought iron, I = 12,400.
,, cast iron, I = 6,200.
,, air space, about I = 6,700.
Magnetising force required :

Air space (2 l. = approx. 1 cm.) = ...	5,350	ampere-turns.
Armature core.....	320	,,
Magnet cores	828	,,
,, yoke	642	,,
Total	7,140	,,

This machine was not originally designed to be self-regulating when running with a backward lead, and, consequently, the width between the magnet cores only allows of an angular breadth embracing 2½ to 3 sections of the armature to assist the forward induction. In Fig. 10, curves 1 and 2 show the performance of the machine as a generator when run with backward and forward



Backward constant lead 920 Rev's per Min. Curves
Forward increasing lead 980 Rev's per Min. Curve 16

EMF in Volts
Current in Amperes

Fig. 11.

lead. With backward lead the position of brushes remains unchanged with all loads. The E.M.F. on open circuit is 100·5 volts at 920 revolutions per minute, at full load 95 volts. Thus, allowing 3 volts for drop in armature and brush connections, the E.M.F. generated at constant speed of 920 revolutions per minute is 2·5 volts less with full load than on open circuit. With forward lead the E.M.F. is 100 volts on open circuit at a speed of 980 revolutions per minute, and 88·8 volts at full load. Allowing 3 volts for drop, as before, the E.M.F. generated is 8·2 volts less with full load than on open circuit, and the brushes require shifting through a total angle of about 35deg. between no load and full load.

Tables V. and VI. give the readings from which the curves 5 and 6, Fig. 11, are plotted. In the experiment the E.M.F. was kept as nearly as possible constant, the results with constant speed being calculated therefrom. Run with a forward lead the machine displays the drop inevitable with a rather short air-space.

I think I am, perhaps, entitled to say that all the machines I have made have been made to fill orders, which they have successfully done. So far, my experience has been that the shorter the air-space the better as regards sparking and fixity of the collecting position. If solid magnet cores are used, as they must usually be on account of the expense of laminated cores, the length of the air-space is limited by the width of the slots. In this connection I have found that the slots may be 1·5 times the length of air-space without any appreciable heating of the poles or waste of power from eddy-current in them. If the armature is wound over with iron wire of sufficient thickness compared with width of slot, or if

the conductors are in tunnels, the length of the air-space can be fixed having regard to mechanical considerations only. In this connection, however, it is necessary to take into consideration the unequal pull of the keepers, or magnets, if the armature is a little out of centre ; for, unless the shaft is very stiff, this may be sufficient to cause the armature to touch against the keeper when excited.

My machines, made by Messrs. Mavor and Coulson, of Glasgow, of course, run with a forward lead as motors, the forward armature turns still increasing the induction. I have, perhaps, hardly laid sufficient emphasis upon the fact that increase in the armature current increases the strength of the flux-horn, and so tends to automatically bring about the sparkless reversal of the sections without any shifting of the brushes. I think it will be abundantly clear that, so far from having fully described what may be done by means of my device for bringing the commutation of ring and drum armatures under independent control, I have only touched on the border of a new field of design for continuous-current machines.

PARLIAMENTARY INTELLIGENCE.

Edinburgh Improvement Bill.

This Bill came last week before the Police and Sanitary Regulations Committee of the House of Commons, presided over by Mr. Walter Long. Mr. Balfour Browne, Q.C., Mr. Cripps, Q.C., and Mr. Comrie Thomson (instructed by Mr. A. Beveridge) were counsel for the Edinburgh Corporation ; and Mr. Pember, Q.C., and Mr. Moulton, Q.C., appeared for the only petitioners, the National Telephone Company, who claimed to have provision inserted for their protection against and compensation for damage.

Mr. BALFOUR BROWNE, in stating the case for the Bill, said that with regard to Clause 24, providing for the alterations of sewers and gas and water pipes, and interference with wires or other apparatus laid down for telegraphic or other purposes, the National Telephone Company, who were now the only petitioners against the Bill, had overhead wires in Edinburgh attached to certain posts, which were erected on private property, and they came before the Court of Referees and asked either to be put in Clause 24, so that if their wires were touched they might get compensation for damage, or to get a separate clause giving them protection. The Chairman of that Court said he did not regard these people as landowners, or as having any lease or easement in land. They were mere licensees, but they were carrying on their business lawfully, and their wires were in a lawful situation, from which they could not take them down. What they were proposing to do was not something which in the ordinary sense might prejudicially affect their wires without touching them, but they were positively going to physically interfere with them and take them down, and the question was whether that did not give them a reasonable right to be heard. A *locus* was given, but he (Mr. Balfour Browne) asked the Committee to refuse the request of the petitioners, and he defied his learned friend to show any law which gave the licensee any compensation. There were only three cases in which their wires would be affected by the Bill. In one case, the property belonged to the Corporation, which could take away their licence at pleasure. In the other two cases the licences were only for a few weeks or months. The importance of this case was that, if the Telephone Company got a compensation clause, the Committee would be practically stepping in between the licensee and the licensor, and giving the former a right beyond what the latter gave him. The claim was an absolutely new departure. This Telephone Company was spread all over the country, and in the case of every other town they would be able, if they succeeded now, to demand the same right. The Corporation, if they purchased the two other properties by agreement, would be in the same position as the landlords, who could withdraw the licences they gave without compensation. Under the circumstances, he asked the Committee not to give the Telephone Company any protection whatever.

Mr. COOPER, borough engineer, was then called with reference to the petition of the National Telephone Company. In reply to Mr. Balfour Browne, he said in only two cases would the taking down of property by the Corporation affect the Company. The other case where they were affected was the City Chambers, which it was not proposed to pull down. It was the general practice of the Company to take periodical licences to put up the posts, but he understood there were cases in which they had put the up without leave. If they got a compensation clause inserted, they would be able to get compensation in all cases, whether they had a licence or not. At present the Corporation could carry out improvements without being liable for compensation to the Telephone Company.

Mr. JAMES HALL, house agent, Palmer's-buildings, Edinburgh, examined by Mr. Browne, said he had property passing through his hands of the value of £30,000 a year, and he had frequent applications from the National Telephone Company for permission to make attachments of wires. The general nature of the arrangement made was that the Company upheld the roof and paid a small annual sum, and were always subject to removal. In the case of 76, West Port, to the best of his knowledge the Company did not get permission. They took it. He had a letter to that effect from the owner. He managed the property for the owner, who never interfered. He had acted for the owner since 1882, and made the arrangement personally with the Telephone Company in 1889. As a matter of fact, he had challenged the Company with having put up their poles there without leave or licence, and they admitted it, and came to the arrangement of 1889. Under that arrangement they were subject to removal on a few weeks' notice.

By Mr. PEMBER : Is it true that if the owner had wished, the Company might have been turned out at any time between 1882 and 1889, and as a matter of fact the Company have been there since 1882 ?—Yes.

Mr. BALFOUR BROWNE said he did not propose to call further evidence on this point.

Mr. PEMBER then addressed the Committee for the Telephone Company. He said that the business which the Company transacted was a branch of the public business of the Post Office. Quite early in the history of telephones, when there was an attempt to carry on the business as an ordinary enterprise, the Post Office interfered, took the Company into the law courts, and obtained a decision, since upheld, to the effect that telephony was a branch of telegraphy, that telegraphy was a branch of the business of the Post Office, and that the Post Office as a department had a monopoly of the whole of that class of business. Consequently, the telephone companies took out licences, and became the licensees of the Post Office, to transact that particular branch of the public service. The enormous development of telephonic business made its continuance and easy performance of great importance, first to the Company and next to the public. He admitted that they were not statutory companies, because they had found that an Act of Parliament for their purposes was not necessary. Their system—the cheapest and best they could think of—was to work by overhead wires, and for that they needed no Act of Parliament, because the wayleaves enabled them to manage the thing without application to Parliament. They relied on their common-law rights, and had fixed their wires on houses, and carried them along streets, and so forth. Sometimes they arranged for those licences for a term of years. Certainly, in other cases they were only tenants-at-will. It was impossible for them to have any other tenure. A house-owner would never give a seven, fourteen, or twenty-one years' lease to those wires over his house, because he never knew what he might want to do with his property. The Company were perfectly ready to run such risk of disturbance. But when they came to the case of a public body requiring a Parliamentary power to interfere with them, the question was altogether different. There could be no doubt whatever that the powers sought by this Bill involved serious disturbance to the Company's property and business. This Committee was not concerned with investigating the Company's tenure of the buildings affected. It was sufficient for the Company to say that they were carrying on an extensive and valuable business both for themselves and the public, and that this Bill was for the purpose of demolishing buildings on which the Company depended, and altering streets across which they carried their wires. The contention of the Corporation was that the Company's property they might destroy without compensation. His answer to that was two-fold. First, that the Corporation was not the private owner, and therefore could not do it without Parliamentary powers ; and, secondly, that the private owner would not do it. He submitted that Parliament would not grant powers which would disturb or destroy people's property without granting compensation. It was no answer to say that the Company's property was not statutory property. He had never heard that compensation was confined to statutory property. They owned their property at common law, and common law right was as good as statutory right in this respect.

Mr. BALFOUR BROWNE, in replying, pointed out that the Bill took power to disturb water and gas pipes, but did not seek to disturb wires at all. It was because the Corporation would become the owners of certain property on which a number of wires were fixed that they sought to exercise the rights of owners, and give the Company notice to remove. But what the Company asked was to give them as lessees rights of compensation against the landlord, their lessor. Now, the rule was that compensation was given only in cases where an action would lie. If no action could lie, there could be no compensation ; and that was the case here. But if his learned friend was right, and there was a property for which he was entitled to compensation, he would get it, because the Bill incorporated the Lands Clauses Act.

At this point, after a brief consultation with his colleagues,

The CHAIRMAN said that the Committee did not desire to hear anything more. They were not prepared to entertain the petition of th Telephone Company.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, May 19th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Students' Meeting. Paper to be read : "Primary Batteries in Theory and Practice," by William R Cooper, M.A.

THURSDAY, May 25th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting. Paper to be discussed : "On the Prevention and Control of Sparking of Continuous-Current Dynamos without winding on the Field Magnets ; and Constant-Pressure Dynamos withou Series Winding," by W. B. Sayers, A.I.E.E.

FRIDAY, May 26th.

PHYSICAL SOCIETY.

5 p.m. Ordinary Meeting. Papers to be read and discussed : (1) Discussion upon Dr. Lodge's Paper—"The Foundations of Dynamics" ; (2) "A New Photometer," by A. P. Trotter ; (3) "Notes on Photometry," by Prof. S. P. Thompson, F.R.S. ; (4) "Exhibition of a Vibrating Bar," by C. J. Woodward.

DIRECT-CURRENT DYNAMO DESIGN.

Until the reading of Mr. W. B. SAYERS' Paper at the Institution of Electrical Engineers last week, no radical improvement in the design of direct-current dynamos had been suggested for some years, and manufacturers had begun to think that a state of finality had been reached. The limiting conditions of output were admitted and accepted as inevitable. Heating was practically reduced to the lowest possible amount by lamination of both iron and copper. The demagnetising effect of the armature was easily calculated, and kept within bounds by attention to the length of the air gap and the magnetic density, and the energy wasted in the field excitation was reduced to a minimum. The commercial efficiencies obtained were so high as to leave practically no margin for advance, and the only real difficulty was the sparking. This could be controlled within fairly well-defined limits, which could not be safely exceeded. Electricians, however, were fully alive to the various points in which theory indicated a possible improvement, and from time to time patents were taken out embodying more or less radical alterations in design.

Years before the connection between the back ampere-turns, the cross ampere-turns, and the main field was mathematically demonstrated, attempts were made, chiefly on empirical lines, to stop sparking. Amongst these were auxiliary pole-pieces, compound brushes, auxiliary coils wound around the armature or intermixed with the main winding; all of which, although partially successful, were impracticable from mechanical considerations. In 1890 the independent investigations of Mr. SWINBURNE and Mr. ESSON, gave a fresh impetus to the subject, resulting in further devices—such as MATHER'S compensating magnet, SWINBURNE'S reversing series-coil wound round the leading polar edge, S. J. RYAN'S perforated pole-pieces with windings parallel to the axis of the armatures, and the division of the pole-piece by a vertical air

Digitized by Google

space through its centre. But still these devices cannot be said to have advanced the subject very much.

Mr. W. B. SAYERS in his Paper read on Thursday of last week before the Institution of Electrical Engineers described an invention which will apparently "make history." The Paper was received by the Institution with more than usual enthusiasm, and members spoke in eulogistic terms of Mr. SAYERS' ingenious device; but we think that they have all rather overstated, in their enthusiasm, its probable field of usefulness. We do not think it clear that the design of direct-current dynamos will be revolutionised or even radically altered by it. Broadly speaking, Mr. SAYERS' invention permits the winding of the series turns on the armature instead of on the field-magnets; and, hence, a series dynamo on his principle requires no field windings, and a compound one only shunt coils. This end is attained by connecting the main loops of the armature winding to the commutator bars by means of long connections, which form open circuits excepting when in contact with the brushes—then they carry the whole armature current. These connections are doubled backwards, with reference to the brushes, and form loops under the edge of the flux pole, thereby producing a forward field and, consequently, tending to excite the magnets. By this means it is apparently possible to control sparking, to reduce magnetic resistance and consequent exciting power, and also to raise weight-output efficiency.

It must be borne in mind, however, that no large machine has yet been built on these lines; and, further, it is not clear that the method is desirable for this purpose; experience may show that though the scheme is suitable for small machines, it may not be adapted for large ones. As was pointed out during the discussion, if sparking can be entirely obviated, the only limit to output is heating. But it is well known that large machines at present give more or less trouble from this cause; and hence it is difficult to see how additional windings, causing a further increase of heat however small, can be desirable. The test of this invention, like that of all others, is merely a question of £. s. d. If by means of it the price of machines can be lowered, it must come; but if the contrary be the case, its use will necessarily be restricted. We remark that Mr. SAYERS has not applied this winding to a smooth-core armature, but has confined his experiments to slotted or tunnel cores. Experience with these cores is so varied that it does not seem safe to form a decided opinion until the method has been applied to smooth ones, where we are at once on safe ground. Yet the inclination of the engineer is decidedly in favour of the tunnel armature, a serious drawback to which, in the experience of some builders, has been sparking. If the device will overcome this, a new era for low-pressure direct-current dynamos is probably before us; but it does not seem probable that high-pressure machines can be safely wound in this manner. Mr. SAYERS says that his machines require short polar arcs in order to increase the belt of back ampere-turns, on which the exciting power depends. This points to a diminution of output, for the magnetic resistance is necessarily increased; yet with a tunnel armature the air-gap is so small that probably this loss will be more than compensated for. In a series-wound machine, since the field-magnets will require no windings, they can be made much smaller than usual; and even with a compound-wound machine, as the field-magnets only have to carry the shunt coils, they may be of small dimensions. Another peculiarity of these machines is the large variations of pressure for extremely small alterations of lead. This property may be of use in the regulation of motors, but appears of doubtful advantage for ordinary constant-pressure dynamos. It is probable that motors embracing this new feature will be utilised in traction problems, and they may assist to solve some of the speed-regulation difficulties.

We expect that the adjourned debate on Mr. W. B. SAYERS' Paper, which takes place on May 25th, will throw further light on this interesting invention. In the meantime, we heartily congratulate the author on the successful application of his ingenious device to small dynamos, and also on the hearty reception of his paper at the Institution of Electrical Engineers.

OBITUARY.

EDWARD ALFRED COWPER.

By the death of Mr. E. A. Cowper, a well-known figure is removed from Westminster, and the already scant number of engineers of the old school is reduced. Only a few weeks ago he was taking part in the discussion at the Institution of Civil Engineers on the Paper by the late Mr. Willans, and characteristically advocated the use of the well-understood Prony brake instead of the rather mysterious dynamo for testing engines, nor did he let the opportunity pass for insisting, as he was wont, on the advantages of the steam jacket. Mr. Cowper died on the 9th inst., from acute pneumonia, after a short illness, at the age of 73. He was the son of Prof. E. Cowper, of King's College, the improver of the printing machine. He served a seven-years' apprenticeship at the works of John Braithwaite, of St. Pancras, which he entered at the age of 14 in 1834. In 1847 he assisted in founding the Institution of Mechanical Engineers, becoming an original member of council, and was President in 1880-81. After active work with Messrs. Fox and Henderson he started in practice as a consulting engineer in 1851, joining in the following year the Institution of Civil Engineers, in the affairs of which he continued to take so active a part up to the last. In about 1857, after giving great attention to the subject of the economy of steam, he introduced the jacketed reservoir for compound engines, with the cranks at right angles. This invention, well known as "Cowper's hot-pot," was applied to H.M.S. "Briton" in 1870; the coal consumption on the trial was 1·3lb. per horse-power per hour. The invention of the tension wheel for bicycles and of rubber tyres in 1868 is attributed to him. Mr. Cowper was a thoroughly practical mechanical engineer, and had strong inventive abilities. He became a member of the Institution of Electrical Engineers in 1879, but did not concern himself much with electrical work. In this year, however, he invented the writing telegraph, an instrument which, as far as the co ordinate movements of rods attached to a tracer; of similar movements of a pen; and of a moving band of paper, are concerned, are identical with the very latest apparatus proposed for this purpose. To all who are in the habit of attending the meetings of the Institution of Civil Engineers, Mr. E. A. Cowper was one of the best known members of council. It was the exception if he did not take part in the discussion on a Paper dealing with a mechanical subject, and he always had some bit of experience to recall, and often an invention of his own to describe with which to illustrate in a most practical manner the topic of the evening. Quite recently he took a keen interest in the display of the diagrams and full-sized models illustrating Mr. Sopwith's Paper on the break-down of the "Umbria," and added greatly to the interest of that discussion. In 1887, in conjunction with Dr. W. Anderson, he made a determination of Joule's equivalent on a large scale, a 5 H.-P. engine being run on a Froude dynamometer for many hours. Mr. Cowper rendered valuable services in connection with the machinery department of the South Kensington Museum, with the Inventions Exhibition, and the Royal Agricultural Society. The times are altering, and such men of mechanical instinct and long experience in a definite branch of a wide profession are becoming rare. The rising generation is more ready to display a knowledge of theory, to spend its strength on the last new thing, and to attempt to cover a wide range; may it give rise to a few men of the sound common sense of Mr. E. A. Cowper.

CHEAP TRACTION OR DEFECTIVE TELEPHONES.

On 26th ult., a meeting was held at the Board of Trade, Sir Courtenay Boyle in the chair (Sir Joseph Warner, Counsel to the Lord Chairman of Committees, being present), at which the Telephone Company and the Electrical Traction Association were represented. The Telephone Company put it to the Board of Trade that, inasmuch as during the past four years they had opposed some fifty Bills in Parliament, with the result that with one or two unimportant exceptions, clauses for their protection had been invariably given either in the form adopted in 1889 in the Lea Bridge case, or in 1890 in the Plymouth case, the time had now arrived when the Board of Trade should accept one of these clauses as a model clause, and take measures to ensure the insertion of such clauses in all Electrical Traction Bills and Orders without further action on the part of the Telephone Company.

The essential portion of the Plymouth and Lea Bridge clauses is the first paragraph as follows :—

1. The Company shall so construct their electric circuits and other works of all descriptions, and shall so work their tramway in all respects, as to prevent any injurious interference by induction or otherwise with the electric circuits from time to time used or intended to be used by the Telephone Company for the purpose of telephonic communication, or with the currents in such circuits. Provided, that as regards electric circuits erected or laid down by the Telephone Company after the construction of the works of the Company, this sub-section shall only apply if reasonable and proper precautions have been taken in the erection or laying down of such circuits, and if they have not been erected or laid down in unreasonably close proximity to the lines or works of the Company.

Sir Courtenay Boyle having heard the representatives of the Traction Association, intimated that the Board of Trade were of opinion that what had taken place *did not* amount to the establishment of an uniform principle that there should be protective clauses in favour of the Telephone Company. He thought that since 1889 a good deal of knowledge had been gained, and that the Board of Trade would now communicate with the Authorities of Parliament to see whether the matter could be considered and settled, and that in the meantime the Board of Trade would not insert any protection clauses in favour of the Telephone Company.

As an outcome of these communications, a resolution for the appointment of a Joint Committee of Lords and Commons has been passed by Parliament: "To consider and report whether the grant of statutory powers to use electricity ought to be qualified by any prohibition or restriction as to earth-return circuits or by any provisions as to leakage, induction or similar matters, and, if so, in what cases and under what conditions. And if the Joint Committee are of opinion that any such prohibition, restriction, or provision should be enforced, to settle the necessary clauses."

The question for consideration by the Joint Committee is in effect whether the Telephone Company is to have *its present system* protected or not. The form of reference does not at first seem to mean this, but it must be borne in mind that the Telephone Company are at present carrying on their business without statutory authority, and that (save by a general act) Parliament can only legislate by the insertion of clauses into Bills or Orders brought before them by promoters asking for powers to use electric traction. When this Joint Committee meets it is assumed that the whole question of electrical traction and telephones will be considered, and the Committee will either give the Telephone Company the protection for which they ask, or say that any protection shall be conditional upon the Telephone Company amending or altering its system by the introduction of a metallic return or otherwise.

The Telephone Company allege that they have always obtained protection clauses from Parliament since they commenced opposition to those Bills in 1889. This is not quite accurate. Out of 50 cases, protective clauses were inserted in about 40 cases *by consent* (given, no doubt, in many cases to save the heavy expense of a long Parliamentary fight), and it was only in about ten cases that the matter came before the Committee. In the cases fought, the results were by no means uniformly favourable to the Telephone Company.

The evidence given by the Telephone Company may be summarised as follows :—The Telephone Company first showed that the currents used by the Telephone Company were infinitesimal and not likely to do any harm to anybody else. That it was *cheaper* to them to dispense with a metallic return and to take the current back by means of gas-pipes or otherwise, by earth returns. The telephones had been decided to be within the terms of the Telegraph Act, and that, in consequence, telephonic messages, being telegrams, were only a branch of a business which had for fifty years been carried on by means of earth returns, and thereby obtained a prescriptive right to the use of the earth. That the electrical-traction companies quite recently proposed to use earth returns. That the currents required for electric traction were very large and powerful. That leakage from, or the inductive effects of, these currents passing interfered greatly with the telephones. That the Telephone Company's lines could be protected from interference by using a metallic return and twisting the wires. That such steps could, however, only be carried out at enormous and prohibitive cost. That, on the other hand, it was very simple and inexpensive to prevent interference by insulating the conductors used for electrical traction.

The evidence upon which the Telephone Company have heretofore succeeded in obtaining protective clauses will show that the real facts of the case have never been put forward, for it was to the following effect : That the same rules should be placed upon electric tramway cases that had been placed upon the electric-lighting companies. That prevention of leakage to earth was solely a question of expense. That it was perfectly easy to insulate the two conductors in a conduit at an expense of about £40 per mile, whereas to lay down a metallic return to telephone wires would cost an enormous amount.

But electric traction cannot be governed by the rules placed upon electric light, for while nothing is easier than the insulation of electric-light conductors from which the current is taken at fixed terminals, nothing is more difficult than the insulation of electric-traction conductors where the current is taken by the arm of a passing tramcar. In the Folkestone case, where the cost of insulating the tramway conductors was put at £40 per mile, the decision of the Committee was that if the Telephone Company required this done they must themselves pay for it ; but the Telephone Company showed their faith in their witness's estimates by refusing the clause and allowing the Bill to pass without any protection to them. As a consequence, they had to pay the promoters' costs, amounting, probably, to more than the cost (on their estimate) of insulating the tramway conductors.

The telephone service with earth returns is admittedly defective. The use of a metallic return by the Telephone Company is not only possible but would, it is admitted, prevent all interference ; and the only excuse given by the Telephone Company for their failure to make their system perfect by this means is that of expense. On the other hand, it has been shown that the use of electricity as a motive power reduces greatly the necessary cost of tramways, but that in practice it is not possible to insulate the conductors.

The matter resolves itself into the question whether *cheap traction* is to be prohibited in order that a *defective telephone system* may be maintained or whether the Telephone Company should not be compelled to perfect its system, and by that means take away the reproach that its service is not only bad but retards the due progress of other electrical industries. And this is the real question that will have to be submitted to the Joint Committee. *Primâ facie* it may seem that there can be little doubt that the decision will be in favour of the traction interest. But in view of the strong position occupied by the Telephone Company, it behoves all corporations and local authorities and all those who desire to see *cheap traction* encouraged and the telephone service improved to support in every possible way the Electrical Traction Association before the Joint Committee.

MAGNETIC VISCOSITY.*

BY J. HOPKINSON, D.SC., F.R.S., E. WILSON, AND F. LYDALL.

The following experiments were carried out in the Siemens Laboratory, King's College, London, and are a continuation of experiments by J. Hopkinson and B. Hopkinson, a description of which appeared in *The Electrician*, September 9, 1892. In that paper determinations were given of curves, showing the relation between the induction and the magnetising force, for rings of fine wire of soft iron and steel, through complete cycles with varying amplitudes of magnetising force, both with the ordinary ballistic method and with alternating currents of a frequency up to 125 complete periods per second. It was shown that if the induction was moderate in amount, for example, 3,000 or 4,000, the two curves closely agreed; but if the induction was considerable, for example, 16,000, the curves differed somewhat, particularly in that part of the curve preceding the maximum induction. The difference was greater with steel than with soft iron. It was not then determined whether this difference was a true time effect or was in some way due to the ballistic galvanometer. The present Paper is addressed to settling this point. The ring to which the following

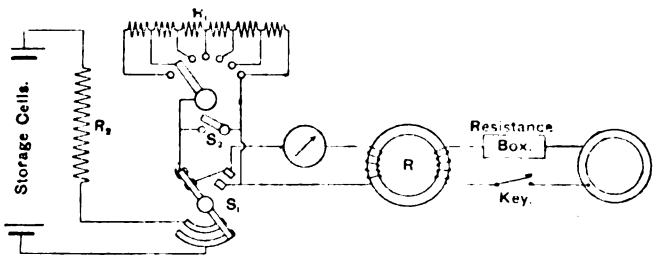

FIG. 1.

experiments refer is of hard steel, containing about 0·6 per cent. of carbon, in the form of wire $\frac{1}{100}$in. diameter, varnished with shellac to insure insulation. The material was supplied by Messrs. Richard Johnson. The ring is about 9cm. diameter, and has a sectional area of 1·08 sq. cm.; it is wound with 200 turns of copper wire, and with 80 turns of fine wire for use with the ballistic galvanometer.

In *The Electrician* paper the static curve of hysteresis was determined by the ballistic galvanometer, the connections being made according to the diagram in Fig. 1, where R is the hard steel wire, B is the ballistic galvanometer, S_1 is a reversing switch, and S_2 is a small short-circuiting switch for the purpose of suddenly inserting a resistance, R_1, into the primary circuit. The resistance R_2 was so adjusted that the maximum current in the primary circuit was such as to give the desired maximum magnetising force on the ring. In taking the kicks on the ballistic galvanometer the method adopted was as follows:—Having closed the primary by means of S_1, the switch S_2 was suddenly opened, thus allowing the

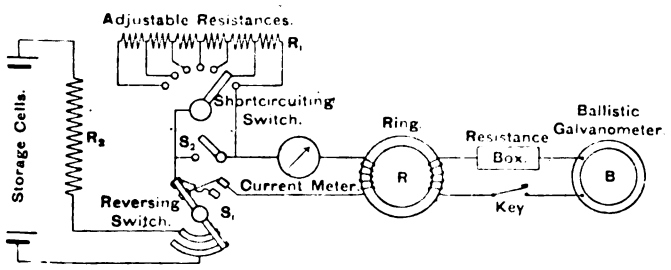

FIG. 2.

magnetising force to drop to an amount determined by R_1, and the kick observed. A total reversal was then taken with S_1, and the kick again observed. The closing of S_2 again brought up the magnetising force to its maximum in the opposite direction to that at starting.

In a letter to the Editor of *The Electrician*, September 16, 1892, Mr. Evershed stated that, "Had the slow cycle been obtained by the method described by Mr. Vignoles,† Messrs. Hopkinson would have found it in almost absolute agreement with the quick cycle curve." To settle this point the static curve of hysteresis was obtained by the ballistic galvanometer, the connections being made according to the diagram in Fig. 2. This is not the method of experiment alluded to by Mr. Evershed, but it is capable of varying the magnetising force in the same way as is described by him. R is the hard steel wire ring, B is the ballistic galvanometer, S_1 is a reversing switch, and S_2 a small switch for the purpose of short-circuiting the adjustable resistance R_1. The difference between this diagram and that in Fig. 1 is that R_1 can be suddenly inserted into the primary circuit by one stroke of the reversing switch S_1. In this way it is possible to vary the magnetising force from one maximum through zero to any desired point within the other maximum by one motion of the switch S_1, which operation takes but a small fraction of a second to perform.

In Fig. 3 the points marked × were obtained by the method in Fig. 1; the points marked · being obtained by the method in Fig. 2. Table I. gives the values for B and H, from which these points

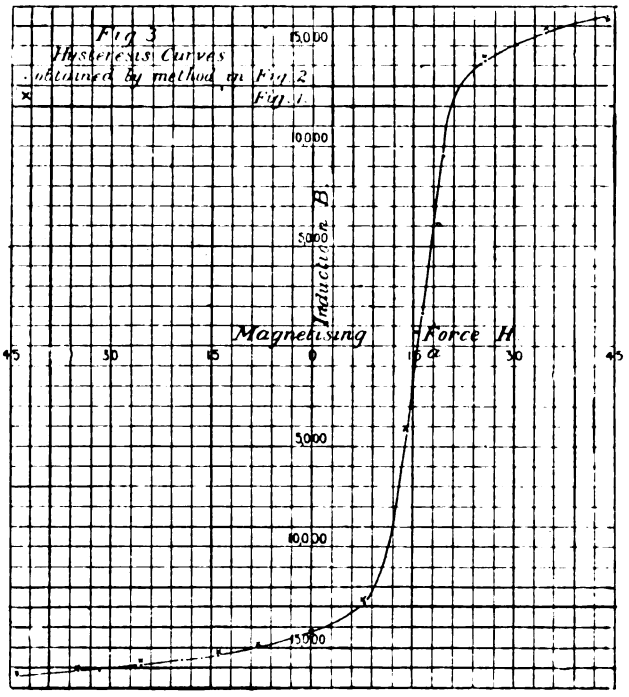

FIG. 3.

have been plotted, and their close agreement proves that the difference found between the static and quick-cycle curves is not due to the cause suggested by Mr. Evershed. In each case the battery used had a potential difference of 108 volts, the periodic time of the ballistic needle being 10 seconds.

Table I—Hard Steel-Wire Ring.

It was observed, when taking the hysteresis curve by the method in Fig. 2, that the sum of the inductions found by varying the magnetising force from one maximum to an intermediate point, and from that point to the other maximum, did not exactly equal the induction got by varying the magnetising force direct from one maximum to the other.

To investigate this with the ballistic galvanometer the magnetising force (Fig. 3) was taken from one maximum through zero to the point *a* by one motion of the reversing switch handle, and the galvanometer circuit closed at known intervals of time *after* such change, the deflection being noted. This deflection does not represent an impulsive electromotive force, nor yet a constant current, but is caused by a current through the galvanometer diminishing in amount somewhat rapidly. It might arise from the comparatively slow rate at which the magnetising current changes, owing to the

* Paper read before the Royal Society.
† *The Electrician*, May 15 and 22, 1891.

Digitized by Google

self-induction of the circuit, or it might arise from a finite time required to develop the induction corresponding to a given magnetising force. The former would be readily calculable if the ring had a definite self-induction; in our case it is approximately calculable.

Let R be resistance of primary circuit, E the applied electromotive force, x the current, and I the total induction multiplied by the number of primary turns.

$$E = R\,x + \frac{d\,I}{d\,t}.$$

Now I is known in terms of x for conditions of experiment very approximately, and, roughly, $d\,I/d\,t$ has a constant ratio to $d\,x/d\,t$—is equal, say, to $L(d\,x/d\,t)$; hence the well-known equation

$$E = R\,x + L\frac{d\,x}{d\,t},$$

$$x = \frac{E}{R}\,(1 - \epsilon^{-\frac{R}{L}t}).$$

From our curves we see that induction per square centimetre increases 10,000, whilst magnetising force increases 4. Total induction multiplied by the primary turns, taking the volt as our unit, increases $10{,}800 \times 200 \times 10^{-8}$, whilst the current increases $\frac{1}{2}$ an ampere, *i.e.*,

$$L = 4{\cdot}32 \times 10^{-2}.$$

In the experiments made E = 4 and 108 volts and R = 0·8 and 21·6 ohms, whence

$$x = 5\,(1 - \epsilon^{-\frac{80}{4{\cdot}32}t}) \text{ and } 5\,(1 - \epsilon^{-\frac{2160}{4{\cdot}32}t}).$$

In either case x does not differ sensibly from its final value when $t = \frac{3}{5}$ second. Hence the self-induction of the circuit can have nothing to do with the residual effects observed.

These experiments showed that an effect was produced upon the galvanometer needle, appreciable for some seconds, the effect being somewhat more marked with 4 than 108 volts. But the whole amount was so small as to be less than 1 per cent. of the total change of induction; from which we infer that no material difference exists between curves of induction determined by the ballistic galvanometer and the inductions caused by magnetising forces operating for many seconds.

Effect of tapping the Specimen.—Having taken the magnetising force from its maximum through zero to the point *a* as before, the effect of tapping was marked, especially in the case of soft iron, when a kick corresponding to an acquirement of 633 lines of induction per square centimetre was observed.

The following experiments on the hard steel wire ring were carried out with the alternator, the object being to ascertain if a time effect on magnetism exists. The ballistic curve (Fig. 3) has been taken as a standard with which to compare the respective hysteresis curves. In each case the maximum magnetising force has been made as nearly as possible to agree with that used when taking the ballistic curve, and the method of test was that employed in *The Electrician* paper. For the sake of completeness the diagram, Fig. 4, and description are given over again. Quoting from that paper, we have:—"For determining the points on the closed curve of magnetisation given by rapid reversals of the current in the coil, the ring was connected in series with a non-inductive resistance to the poles of an alternate-current generator, or a transformer excited by the generator, thus:—

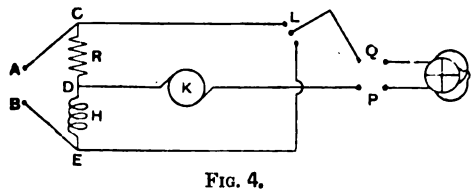

Fig. 4.

in which A B are the poles of the transformer or generator; C D the terminals of the non-inductive resistance R; H the coil surrounding the ring; P and Q the studs of a reversing key connected to the quadrant of a Thomson quadrant electrometer; L a key by means of which Q could be connected with C or E at will; and K a revolving contact maker, through which P was connected to D. A condenser was connected to P and Q, in order to steady the electrometer readings. The contact maker K was bolted on to the axle of the generator. It consists of a circular disc of ebonite, about 13in. in diameter, having a small slip of copper, about $\frac{1}{10}$in. wide, let into its circumference. A small steel brush presses on the circumference, and makes contact with the piece of copper once in every revolution. The position of the brush can be read off on a graduated circle. The quadrant electrometer thus gives the instantaneous value of the difference of potential between the points C and D, or the points D and E, according to the direction of the key L."

Frequencies of 5, 72 and 125 ∿ per second have been tried, two values being given to the potential difference at the terminals of the alternator in each of the frequencies 72 and 125, making in all five complete experiments. The curves so obtained are given in Figs. 8, 9, 10, 11 and 12 respectively. From observations of the values of the electromotive force between C and D (Fig. 4) at different times in the period, a curve A (in each experiment) was plotted, giving the magnetising force in terms of the time; a similar curve was plotted for the electromotive force between D and E, which, when corrected by subtracting the electromotive force due to the resistance of the coil H, gives the potential or time rate of variation of the induction in terms of the time. Hence the area of this curve (B) up to any point, *plus* a constant, is proportional to the induction corresponding to that point. This is shown in curve C, which is the integral of B. In each of the five experiments the ring with the non-inductive resistance was placed across the terminals of the alternator, and the excess of potential taken up by a non-inductive resistance.

In Fig. 5 the hysteresis curves for frequencies of 5, 72 and 125 are compared with the ballistic curve. These curves are marked 5, 72L, and 125L respectively. The corresponding values for B and H, from which these curves have been plotted, are given in Tables II., III., V., which have been obtained from the curves in Figs. 8, 9, and 11 respectively.

7,027	14·3	16,219	40·9
10,121	12·6	16,245	45·7

The most noteworthy features in these curves are that the curve with a frequency of 5 is very near the ballistic curve, if allowance is made for difference in the magnetising current, and that the

Digitized by Google

curves with a frequency of 72 and 125 deviate very materially, particularly in the part of the curve somewhat preceding the maximum induction. Hence, the time effect mainly develops with a greater frequency than 5 per second. Hence also, we infer that this effect, as already described in *The Electrician*, is a true time effect, not arising in any way from the ballistic galvanometer.

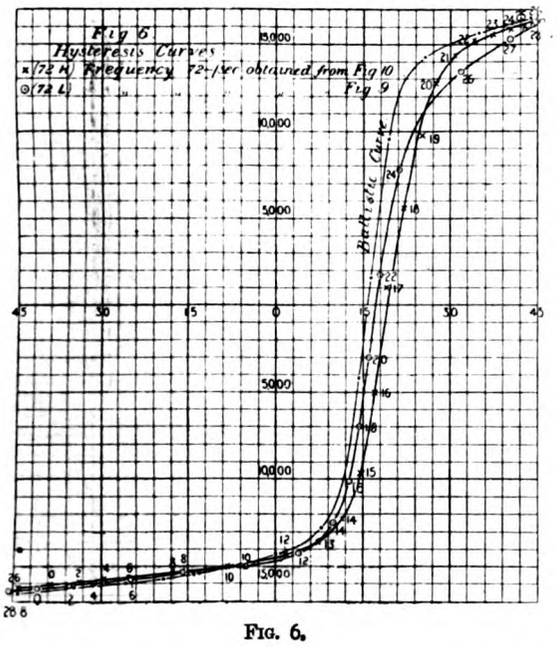

FIG. 6.

In Fig. 6 the hysteresis curves for a frequency of 72 are compared with the ballistic curve. The curves are marked 72 L and 72 H respectively, the potentials at the terminals of the alternator in the two cases being, approximately, 36 and 430 volts. The corresponding values for B and H are given in Tables III., IV., which have been obtained from the curves in Figs. 9 and 10 respectively.

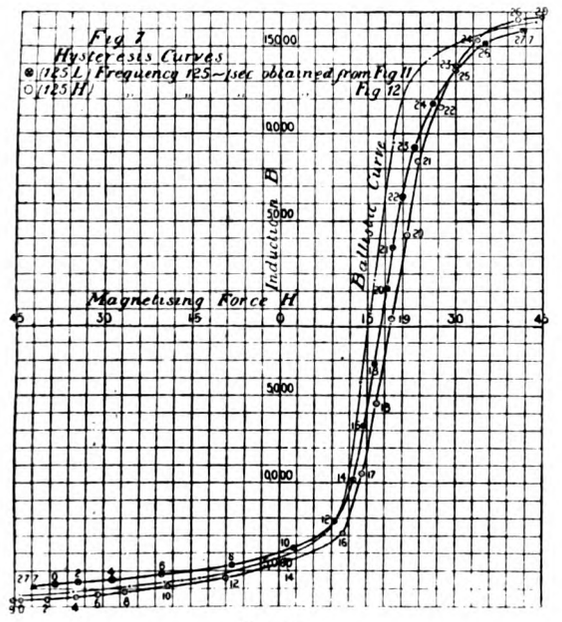

FIG. 7.

The difference between the two curves in Fig. 6 was at first puzzling, but a little consideration satisfied us that it arises from the same time effect. The curve 72 L was determined three times, with the same result. The numerals refer to thirtieths of a half-period. From 26 to 28·8 of the L curve the magnetising force increases from 31·8 to 45·6, whilst from 21 to 26 of the H curve it increases from 30·6 to 44, the rate of change being about double as great in the former case as in the latter, and it is the L curve which deviates most from the ballistic curve. In like manner, in the neighbourhood of zero induction the induction in the H curve is changing twice as fast as the induction in the L curve, and it is here the H curve which differs most. How these differences of rate of change arise can be seen by inspecting Figs. 9 and 10.

In Fig 7 the hysteresis curves for a frequency of 125 are compared with the ballistic curve. The curves are marked 125 L and 125 H respectively, the potentials at the terminals of the alternator being approximately 62 and 750 volts. The corresponding values

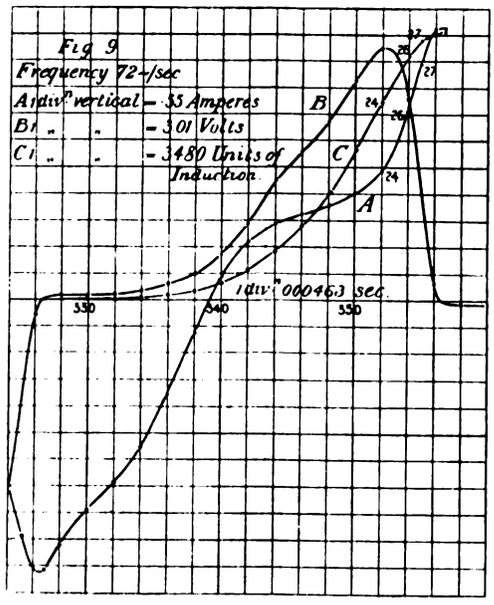

Fig 9.

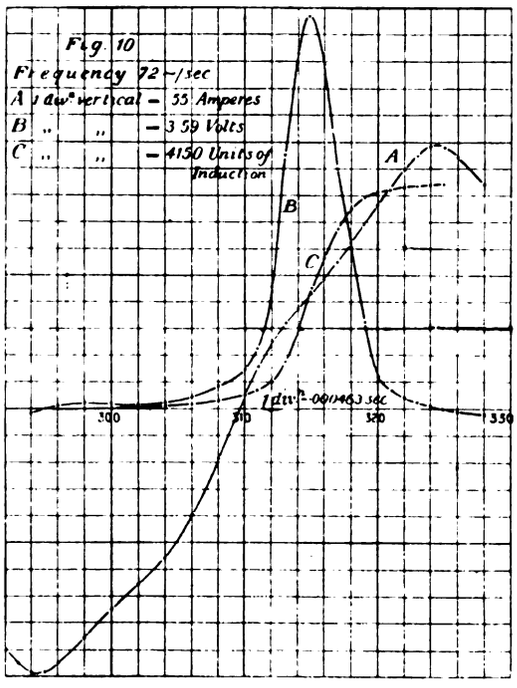

Fig. 10.

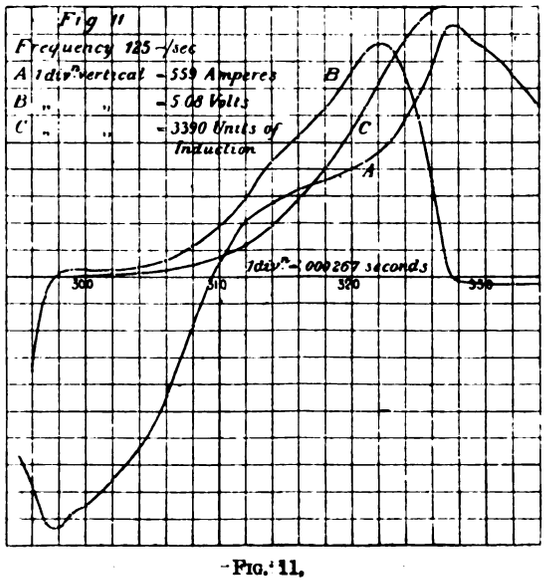

Fig. 11.

Experiments have been made upon chromium steel, supplied by Mr. Hadfield, having the following composition :—0·71 per cent. carbon, 9·18 per cent. chromium, when annealed, and when hardened by raising to low yellow and plunging into cold water. The results show that the same time effect exists in this case, although it was not so marked as in the case of the hard steel.

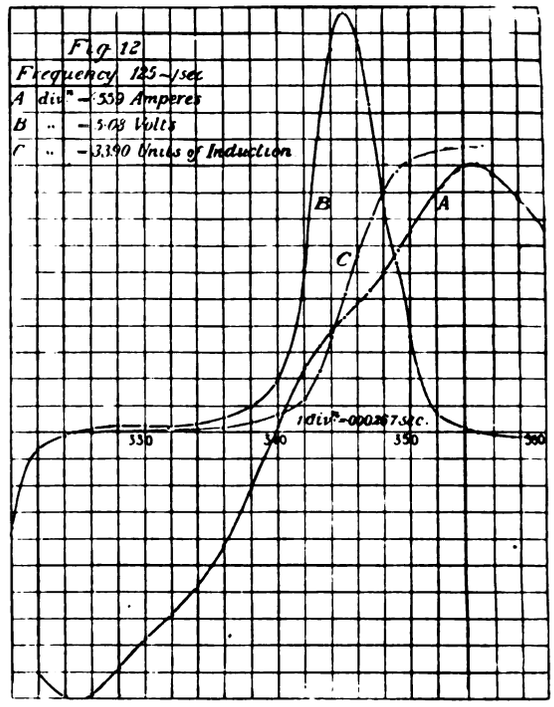

Fig. 12.

We draw the following conclusions from these experiments :—(1.) As Prof. Ewing has already observed, after sudden change of magnetising force, the induction does not at once attain to its full value, but there is a slight increase going on for some seconds. (2.) The small difference between the ballistic curve of magnetisation with complete cycles and the curve determined with a considerable frequency, which has already been observed, is a true time effect, the difference being greater between a frequency of 72 per second and 5 per second than between 5 per second and the ballistic curve.

THE INTERDEPENDENCE OF ABSTRACT SCIENCE AND ENGINEERING.*

BY WILLIAM ANDERSON, F.R.S.

(*Concluded from page 40.*)

It is not often that a genius of the order of James Watt rises in the mechanical world. Up to the time when the University of Glasgow required its model of a Newcomen engine to be repaired, the "fire-engine," as it was most properly called, was being slowly developed without any exact knowledge of the properties of the agent by means of which the heat generated by the combustion of fuel was converted into work, and this in spite of the circumstance that such a master mind as that of Smeaton had been directed to perfecting the new method of utilising the potential energy of fuel, and of applying it to engines of large power, and on an extensive industrial scale.

The bent of Watt's mind was characterised by a love for abstract science, and it was, no doubt, for that reason that he abandoned his father's business and took up the profession of a philosophical instrument maker, in the pursuit of which he naturally came in contact with the meagre knowledge of physical science of the period, and with men eminent in the world of learning and of research.

The lucky chance which presented itself of having to put in order a working model of a Newcomen engine, illustrates in an interesting manner how, in pursuance of his business, he quickly executed the necessary repairs and alterations, and afterwards, at greater leisure, attacked the problem which the failure of the model presented from the theoretical side, but soon found that the then state of knowledge did not afford the means of explaining the

* Abstract of the "James Forrest" Lecture, delivered before the Institution of Civil Engineers, May 4, 1893.

Digitized by Google

failure, and compelled him to set about the determination of such elementary data as the specific volume of steam, the latent heat of evaporation and the law of tension of steam under varying temperatures. In the astonishingly short period of two years, and with the rudest and cheapest apparatus, he had furnished himself with the abstract knowledge required for explaining in a definite manner the action of the steam engine, and he had no difficulty, as soon as his theoretical ground was sure, in determining what mechanical arrangements were necessary to realise the conditions imposed by science. From investigations, apparently of an abstract or non-practical character, sprung at once the separate condenser, the closed cylinder and the equilibrium working of a single-acting engine, the steam-jacket, the air-pump, the theory of expansive working, the function of the momentum of the moving parts, and the exact calculations based on first principles by means of which the proportions of engines could be fixed, and the quantities of steam, water, and of fuel calculated. Watt, of course, was a born mechanic, as well as a seeker after physical knowledge. The workshop in his private house near Birmingham, happily preserved to this day as he left it, shows that his mind was ever bent on mechanical contrivances which his own hands were skilful enough to carry out; his valve-gear, the stuffing box, the parallel motion, the governor, are all instances of that happy blending of mechanical skill and of scientific research which must ever mark the qualifications of a great mechanical engineer.

A contrast to Watt's achievements is the singular history of the development of iron and steel bridge building, which necessarily followed the introduction of railways. Watt felt the want of first principles by which to shape his actions, and set about discovering them; but the principles which underlie the determination of stresses in braced structures, such as roofs and frameworks of various kinds, as well as those in solid bars subjected to the action of transverse forces, have long been known; and early in this century Navier made them the subjects of lectures at the Ecole des Ponts et Chaussées, yet engineers in this country seem to have been but dimly aware of them, or, at any rate, to have made little use of the knowledge which was at their disposal. It is difficult, from the published histories of such enterprises as the Conway and Britannia bridges, to arrive at any conclusion as to the extent of knowledge, or rather ignorance, which existed among engineers before these works were commenced. It is probable that some of a specially scientific turn of mind, but who were not in conspicuous practice, had a deeper insight into principles than the men whose great natural genius and knowledge of affairs placed them in prominent positions in the great railway enterprises of the day. It is sufficiently evident, however, from the long series of purely tentative experiments by which the proportions of the Conway and Britannia bridges were determined, as well as from the singular vagaries to be noticed in the smaller bridges of that day, that only the haziest ideas of the disposition of stresses and of the functions of the component members of girders existed. This naturally led to timidity as to the capacity of girders to carry, unaided, the loads it was sought to impose, and induced a preference for masonry or for suspension bridges, with respect to which much wider experience was at command.

In the experimental investigations of the time, the function of the web or vertical member of a girder was completely ignored, for it was looked upon merely as the mean of keeping the top and bottom flanges in their relative positions, while the essential difference in effect of a uniformly-distributed load, or of a rolling-load, as compared with a load concentrated at the centre, on the vertical member of a girder, and even on the flanges, appears to have been overlooked till made evident by the results of experiment; and the grave doubts which arose as to whether the girders of the two great tubular bridges could be made self-supporting are apparent to this day in the preparations made in the piers and abutments for the introduction of auxiliary chains. Yet the principle that a force cannot change its direction unless combined with another force acting in a direction inclined to it was perfectly well-known, and should have led to the discovery that it is only by diagonal stresses in the vertical members that the load resting on a beam can be transmitted to the abutments; that the stresses due to loads concentrated at the centre were very different to those arising, both in the vertical web and in the flanges, from the action due to a load distributed in a given manner along the top or the bottom flanges, and that a rolling load would produce effects peculiar to itself.

The girder with diagonally-braced webs, or the lattice girder, as it is commonly called, appears to have had its origin in Ireland; at any rate, it was in that country that it received its earliest and chief development; but at first, as illustrated by the bridge which used to carry the Dublin and Drogheda Railway over the Grand Canal in Dublin, it was a mere attempt to substitute for plate webs an arrangement of flat bars sloping in opposite directions, placed very close together, and having the oppositely-inclined bars connected at their intersections by countersunk rivets.

Since 1848 the supremacy of theory over rule of thumb has gradually but surely asserted itself, though, at times, the want of common sense and experience in the application of abstract principles, as well, perhaps, as ill-judged efforts to produce cheap structures, has led to disasters quite as serious as those which arose from want of theoretical knowledge; and in this respect the competent and successful engineer will still show himself as the man who, in his work, is careful to make theory and practice walk side by side, the one ever aiding and guiding the other, neither asserting undue supremacy. This course, in its highest development, we may, I think, assert is that adopted by our leading engineers, with the result that this country may claim the honour of such a structure as the Forth Bridge, for the design and construction of which no tentative experiments were needed, though the form and mode of construction were very special, if not absolutely new, and the dimensions, both in span and height, so gigantic that the authors of the design could have derived but little aid from previous experience.

The history of scientific research teems with instances of discoveries which at first seemed to have had no practical value, but which nevertheless have ultimately proved to be of the utmost importance to the engineer. Notwithstanding such experience, and even in these days, there are so-called practical men who are utterly intolerant of either time or money being devoted to investigations which seem incapable of bearing immediate fruit. Many examples might be cited, for instance: the changes of temperature which occur in many chemical reactions were merely noted, at first, as interesting accompaniments to such reactions; but, by degrees, it was perceived that the amount of heat evolved or absorbed in each chemical change was a constant and definite quantity, which was capable of exact measurement, and in process of time the thermal values which characterised a vast number of chemical changes were determined, and are now considered of cardinal importance in many industrial operations, and constitute the science of thermo-chemistry.

At the same time, the total heat of evaporation of water and of other substances was ascertained with great precision, so that it became possible to judge of the efficiency of a boiler, for instance, when the rate of fuel combustion and that at which the water was heated or evaporated were known, by calculating the proportion which the heat imparted to the water bore to that produced by the combustion of any fuel of which the chemical composition had been ascertained, and from which the heat capable of being developed could be calculated by general rules, and thus researches in the chemical and physical laboratories have had the ultimate effect of placing the theory of the steam-engine on a firm basis.

One practical effect of the exact knowledge which every competent engineer now possesses on this subject, or can easily obtain, is that inventors have ceased to squander their time and their means in seeking for impossible high boiler duty, and the public is no more entreated to try contrivances which are to save at least 50 per cent. of the fuel they use, because inventors know that the testing of boilers is now usually carried out by experienced and educated men, who, by very simple and inexpensive trials obtain the data by means of which they can calculate with certainty how much scope for improvements actually exists.

Still more remarkable, perhaps, is the application of thermo-chemistry to the complicated reactions in the blast furnace, and the valuable conclusions arrived at in consequence by such thorough and patient investigators as Sir Isaac Lowthian Bell, Charles Cochrane, and others, who have succeeded in equating the heat-units resulting from the oxidation of fuel to the ultimate thermal results of the decomposition of the ore and fluxes, showing thereby the limits of economy which the ironmaster may hope to reach, and the proportions of the furnaces in which his expectations may be realised.

No less valuable have been the fruits yielded by the discovery of the great law of the Conservation of Energy, and by the recognition of the fact that, though energy cannot be destroyed, it may be made to assume various forms, and may be rendered either dormant or active. The sun's rays, æons of ages ago, during the dense vegetation which charactised the period of the coal measures, expended their energy in tearing asunder the carbon and oxygen of the carbonic acid so sparsely distributed though the atmosphere, and in storing the carbon, thus endowed with potential energy, in the deposits whence we now derive our coal supplies. By suitable arrangements this dormant energy is quickened into that quality of motion which we recognise as heat, and which, setting into sympathetic vibrations the material of the furnace-plates and smoke-flues of boilers, operates on the surrounding water, the molecules of which, under this influence, assume the more extended movements of the highly elastic substance which we know as steam. The products of combustion, on the one hand, are restored to the atmosphere, their remaining store of heat is slowly dissipated, while the carbonic acid gas produced in combustion is again ready to present itself, in the green leaves of plants, to the decomposing action of the sun, and by that means the carbon and the oxygen become once more sources of heat. The steam produced, on the other hand, communicates its molecular motion to external bodies in various heating operations, in

Digitized by Google

the visible motion and force of the steam-engine or into the slower dissipation through space or over the earth, whereby it is again condensed to water and returned to its normal condition, while the energy, for the exhibition of which, Carnot has taught us, steam was the mere agent, becomes transformed into masses of water lifted, into air compressed, into electrical currents generated, into mechanical work done, or into the heat developed by friction; but the general tendency is towards dissipation under the form of heat into space, the waste being made good by the stores of heat poured on to our planetary system by the huge and mysterious body which is its centre. Whence this enormous and apparently unfailing supply of heat is derived has been, and still is, the subject of most interesting controversy, the upshot of which seems to be that the heat developed by the shrinkage of our luminary and by the fall on to its surface of meteoric matter is sufficient to keep up the supply, at any rate for many thousand years.

But modern investigators, and, most of all, engineers, are not content with vague statements such as I have just made; they hold with the motto of the ancient Society of Civil Engineers, "Omnia in numero pondere et mensura," and they are, therefore, greatly indebted to Rumford, Carnot, Davy, Mayer and Joule, who not only showed that heat was a "mode of motion," but determined by tedious and delicate experiments its mechanical equivalent.

And what is now the result?

When examining heat-engines or other applications of heat in the arts, the engineer collects the apparently aimless work of half a century, and of many minds, and finds himself able to construct a balance-sheet by which he can show on the Dr. side, to a fraction, the quantity of heat he has received, and on the Cr. page, with astonishing precision, the manner in which that heat has been expended. This method of treatment is not only lucid, but it is self-checking, and it points out how much heat has been uselessly dissipated, and, consequently, in what direction improvements may be made, and it indicated, further, the limits within which it is alone possible to make advances in economy.

One of the loftiest of abstract conceptions relation to the structure of the universe, the product of many acute minds of this century, is the imagining of a substance of infinite tenuity but of immense elasticity, which permeates all space and every substance. It cannot be seen, or felt, or weighed; its composition is unknown; it cannot be pumped out of a closed vessel; itdoes not appear to offer any resistance to the motion of planetary bodies, and its existance is only made manifest by its property of transmitting chemical rays, light, radiant heat, electricity, and probably some more recondite forms of energy, at enormous velocity from the remotest regions of the universe and by means of vibrations the nature of which, the astounding frequency and minute pitch, have been determined by mathematicians. It is pardonable in human beings to disbelieve in the existence of the luminiferous ether, even though the profoundest thinkers and most successful workers of the present day may have all the conviction of Lord Kelvin, who has declared that "it is the only substance that we are confident of in dynamics; the one thing we are sure of is the reality and substantiality of the luminiferous ether!"

But what has the engineer to do with such speculations, and what does it matter to him how light and heat are transmitted from the sun or from the stars, or by what mechanism heat, magnetism and electricity are diffused over the earth? This question is being answered already in our daily practice, and is destined, no doubt, to receive fuller and more convincing response as time rolls on.

The lecturer then alluded to the results of spectroscopic researches, Mendeleeff's theory of the production of petroleum, and recent metallurgical work, after which he continued:—

I think that it is now generally acknowledged that the luminiferous ether is also the medium by which electrical energy is transmitted by some kind of vibratory motion; hence, the ease with which heat or mechanical work is transformed directly into electric currents in the thermopile, or in the frictional electrical machine, and the reasonableness of the great generalisation that we are living on a huge magnet—the poles of which are not far from coinciding with the poles of the earth. To what purpose are the endless observations on the deviation and dip of the magnetic needle which are so assiduously carried on by every civilised nation, and what interest have engineers in the painful labours of those daring explorers who set up their Observatories amidst the endless ice and the darkness of the Polar regions?

Let such a questioner, if there be one, study the construction of the mariners' compass, and especially in the improved form introduced by Lord Kelvin; let him compare the blind groping after correction for the local attraction of the ship with the beatiful and simple theory which has rendered that correction not only easy but readily adapted to changes in the ship's position in the world; he will find that there is not a more striking instance of the profoundest abstract knowledge blended with the power to turn it to practical use than in this and in so many other labours of the distinguished man whom I have named more than once, and whom this Institution is proud to number among its honorary members.

I will not dwell upon the wonderful results of which we are today reaping the benefit, and which have arisen from the application of the most profound scientific knowledge to the problems which arise in the generation, storage and application of electricity, to the transmission of power, to telegraphy, and to lighting; but I would draw your attention to a startling consequence of the undulatory theory in the power which exists of existing influence, by what is termed induction, at great distances. Animated by the conviction that electric energy was transmitted in the same manner and by means of the same all-pervading medium as radiant energy, and that the distance to which its effects would reach should be unlimited, though the appreciation might be a question of the delicacy of instruments, Mr. Preece has succeeded in sending messages by Morse signals across the Bristol Channel between Lavernock and Flatholme, a distance of over three miles. The electromagnetic disturbances were excited by primary alternating currents, having a frequency sufficient to generate a low musical note in a telephone, in a copper-wire 1,237 yards long, erected on poles along the top of the cliff on the mainland. The radiant electromagnetic energy was transformed into currents again in a secondary circuit 610 yards long, laid along the island parallel to the first and at a distance of 3·1 miles; the messages were read off on the island through the instrumentality of the induced currents, and the experimenter was gratified to find that the results obtained on the secondary wire were in complete accordance with the expectation which theory led him to entertain.

Any one who has meditated deeply on the nature of the luminiferous ether and on its universal presence has probably felt that it must also be concerned in the action of the human brain. The mechanisms of the "five gateways of sense" have been worked out by anatomists and physicists, but their researches are incompetent to declare how the impressions sent along the nerves at last reveal themselves as images or perceptions in the mind. Lord Kelvin has discoursed on this matter; he has suggested the existence of a magnetic sense, and has shown that the mind may be influenced independently of the recognised organs of perception. There are, undoubtedly, occult phenomena which can only be accounted for by the supposition that one mind can interact upon another, even as Mr. Preece's parallel wires acted on each other.

I have already alluded to the circumstance that the engineer cannot be satisfied with vague statements or with mere abstact opinions. The very nature of his calling implies action; he has to construct his works must be stable; his machinery must act; his estimates of cost and of the consequences of his operations must come true; and hence he has to make a close alliance with that most facinating and fruitful of the sciences—mathematics. It is not given to many to possess the peculiar aptitude which leads up the highest investigation, but neither has the engineer often need of anything deeper than almost elementary knowledge, especially if he gets into the habit of working out the problems that come before him by the graphic methods which are now so assiduously cultivated, and if he will realise that slovenliness in the matter of calculations commonly leads to disastrous results. Though his attainments may not be high, and though disuse may have made it difficult to wield the power which knowledge, early acquired, once gave him, yet he can always appreciate and put his faith in the great minds which delight in subjecting the theories of physicists to the rigid test of mathematical analysis, and thereby stamping them with the seal of irrefragable feat.

One great quality he must possess, especially in these days when numerous science colleges have rendered high mathematical training of easy access—and that is common sense. There is a tendency among the young and inexperienced to put blind faith in formulæ, forgetting that most of them are based upon premises which are not accurately reproduced in practice, and which, in any case, are frequently unable to take into account collateral disturbances, which only observation and experience can foresee, and common sense provide against.

I have endeavoured to show how the history of abstract science—by which I intend to designate the history of researches entered into for the sole purpose of acquiring knowledge of the operations of Nature and of her laws, without any thought of reward or expectation of pecuniary advantage—has had its reflex in the records of the engineering profession, and how the most recondite investigations, apparently unlikely to have any direct influence on our practice, have, in course of time, become of cardinal importance. I have also ventured to point out how, in these days, the engineer must banish from his mind the idea that anything can be too small or too trifling to deserve his attention. "Nothing is too small for the great man," is, I am told, written over the cottage once occupied by Peter the Great at Saardam. The truth embodied in that legend should ever dwell in our minds; for success, I am persuaded, lies largely in close attention to details.

Digitized by Google

You may, perhaps, think that I have endowed abstract science with undue importance, and that I have claimed too wide a domain for the engineer. If this be so, I would turn to the old and faithful servant of this Institution, in whose honour it has been a labour of love to prepare this discourse, and ask him for his verdict.

You can anticipate his answer! Who does not know how jealous he is of the honour and prestige of our Institution? Who is not aware that he will not concede that any branch of physical science is beyond its province? Nor will he yield to any of the younger societies more than the position of tributary powers. He is glad, as we well know, to recognise as our children institutions dealing with special branches of the profession; he is glad to foster them in every way, and rejoices to see them meeting under the eyes of the fathers of the profession, whose portaits adorn these walls: but I am confident that he will declare that you cannot touch anything in natural science which will not, sooner or later, prove of advantage to the members of this Institution, and which the engineer will not, in time, turn to the moral as well as to the material advantage of the human race.

LEGAL INTELLIGENCE.

Woodhouse and Rawson, United (Limited).

Four petitions for the compulsory winding up of this Company, which was in voluntary liquidation, came before Mr. Justice Vaughan Williams on Wednesday.

An application had previously been made to the Court, three petitioners appearing, for a winding-up order under the order of the Court, but as Counsel acting on behalf of creditors objected to a supervision order on the ground that it would prejudice their position, and pressed for a compulsory winding up, the matter was adjourned in order that the creditors so objecting might appear as petitioners. Sir Horace Davey, Q.C., was present on behalf of the liquidator appointed in the voluntary winding-up.

Mr. WHEELER said originally a petition was made by a debenture stockholder, for whom he appeared, for the compulsory winding up of the Company. A question of law arose as to whether his client was really a creditor and had a right to appear, and that question had not yet been settled. The other petitioners agreed to accept a Supervision Order, and he was instructed to say that his client was also, in the circumstances, agreeable to that course. There was opposition to the Supervision Order on the behalf of creditors, and the petition was ordered to stand over in order that it might be ascertained how far a new rule, which had only just come into force, would apply.

Mr. UPJOHN appeared for a creditor, and asked for a Compulsory Order, but Mr. WILKINSON, who appeared for a number of creditors and debenture holders, preferred a Supervision Order, as also did Mr. ARCHIBALD, who appeared for a creditor who had filed a petition against the Company so far back as March last, and who asked that costs should not be allowed on the other petitions.

Sir HORACE DAVEY said the whole question resolved itself into a question of costs. He appeared for Mr. Young, the voluntary liquidator, and notwithstanding the statements made in Mr. Upjohn's petition, he submitted that it was not Mr. Young's intention to take any part in the discussion as to whether there should be a voluntary or a compulsory winding up. There was a scheme for the reconstruction of the Company, but Mr. Young said nothing as to the probability of that scheme meeting with acceptance of the shareholders and creditors. In an affidavit made by Mr. Leslie, the Receiver appointed in a debenture-holder's action, he stated that he valued the assets of the Company at about 50 per cent. of the debenture stock; his valuation was something like £117,000, and the amount of debenture stock was about £200,000, so that if that valuation was correct, there was only enough to pay 10s. in the £ to the debenture-holders, who had the first charge. There were claims against the Directors, but the highest estimate he had heard as to these claims was £87,000, so that, assuming the full amount was recovered, there would still be insufficient to meet the claims claims of the debenture-holders, and in that case he was afraid Mr. Upjohn's client would have to be content with the knowledge that he had discharged what he felt to be a public duty gratuitously, and with the reflection that virtue was its own reward. With regard to costs, there had been five petitions filed, although there were really only four before the Court. If his Lordship thought fit to make a winding-up order, it was an important question in principal, though perhaps an academic one, whether more than the first two petitions were necessary.

His LORDSHIP asked to what extent the reconstruction scheme would be possible under a compulsory winding-up order.

Mr. UPJOHN said there was provision in the Act to allow of a compulsory winding up to be stayed if necessary. Mr. Leslie's estimate of the assets of the Company, seeing that he was acting for the debenture-holders only, was not likely to be an excessive one; was, indeed, much more likely to be too moderate. The actual amount of the debenture stock was £180,000; and, even upon Mr. Leslie's estimate of £117,000, and with the £87,000 which had been stated as the amount claimed from the Directors, there would be an actual surplus for the benefit of the creditors. They hoped, with such means of investigation as his lordship could give them, to increase that.

His LORDSHIP said he was of opinion that he ought to make the compulsory order that was asked for. He proposed to make the order, as he understood he had the right to do, upon all the petitions that were before him; but he did not propose to allow costs on all those petitions. His view of the matter was that if it had not been for the presentation of a fourth petition, the compulsory order which he was now going to make would not have been made at all. He should, therefore, allow costs on the petition of Charles Ebenezer Challis, Mr. Upjohn's client, alone. This was a liquidation in which he was not at all satisfied but that there might be a large surplus after all the claims of the debenture-holders were satisfied. Persons in the position of the Receiver, Mr. Leslie, were extremely apt to underestimate the assets in the interests of the debenture-holders, and it was frequently the case that the debenture-holders included amongst their number persons who, if they were not Directors or officers of the Company, or vendors to the Company, or promoters of the Company, were really connected with those classes, and their interest was that there should be as little public investigation, as well might be. They very naturally pressed their views upon the Receiver, who acted for the debenture-holders, as to the small amount likely to be realised by the assets, and the Receiver, not unnaturally, adopted their views. In this case, the Receiver admittedly had not taken into consideration the large claims which it was said might be made upon the Directors. It was impossible for anyone to judge with any accuracy what the amount of such claims might be, although £87,000 had been mentioned; all it was possible to say was that there were large claims, and they should be taken into consideration when dealing with the question of whether there ought to be an order at the instance of the creditors. The conclusion he had come to was that it was impossible that there could be any certainty even in regard to the probability that there would be no surplus after the debenture-holders were satisfied; on the contrary, on the evidence he was convinced that there probably would be a surplus. Thus, the creditor having clearly a *locus standi*, as there was reasonable prospect of something coming to him under the liquidation, consequent upon a compulsory winding up, the only other question he had to consider was whether the mere fact of the existence of a voluntary liquidation ought to prevent him from making the order for a compulsory winding up, and he thought not, because he was clearly of opinion that, having regard to the nature of the assets, having regard in particular to the large claims against the Directors and others who had been concerned in the management of the Company, it would be a serious prejudice to the creditors if the voluntary liquidation were allowed to proceed. He did not, for a moment, mean to suggest that Mr. Young, the liquidator, would not, on his part, do everything which he ought to do to ascertain what claims the Company had which might be realised; but the real fact of the matter was that Mr. Young, as the voluntary liquidator, had not the means to hand which the Official Receiver had for making the necessary enquiries. In a case like the present, where there were charges made against those concerned in the promotion and management of the Company, charges which might have some foundation in fact and might turn out to be true, it was plain that it was a case for strict inquiry, and under the circumstances it seemed to him that, however anxious Mr. Young might be to perform his duties efficiently, it was impossible that he should be able to perform them with the efficiency that an Official Receiver would be able to do. He therefore made the order for the compulsory winding up.

National Telephone Company (Limited) v. Harston.

In the Sheffield County Court last week an action was brought by the National Telephone Company against Mr. G. Harston, a tradesman, of Glossop-road, Sheffield, for £45, being the rent of a telephone from 1891 to 1893. It appeared that in January, 1889, the defendant entered into an agreement with the Sheffield Telephone Exchange Company for wires to be supplied to his shops and mill at a charge of £7 per wire per annum. In the following August the plaintiff Company purchased the Sheffield Company's exchange business, and took over the defendant's debt. £24. 11s. 4d. was paid into Court, the defendant contending that under his agreement this was all he was liable for, as attached to the agreement was an undertaking that if any reductions were made in the legal rates the defendant should have the benefit of such reduction. In January, 1891, the plaintiff Company reduced their general charges from £10 to £7, and the defendant claimed that, although he was only paying the £7 per cent., he was still entitled to this reduction of £3 per cent. per wire, the plaintiff Company, however, contending that the reduction referred to did not apply to such lessees as the defendant, but only to persons paying over £7. The question, therefore, was to decide whether the plaintiff Company were justified in claiming the full amount, or whether, under the circumstances, the defendant was legally entitled to the abatement claimed.

Judge ELLISON, after hearing the evidence, and remarking that the defendant had paid more into Court than was necessary if his version were the right one, reserved judgment.

Lindsay v. Cowper.

This case, which came before Mr. Justice Lawrance and a Common Jury last week, was one in which Sir Coutts Lindsay sought to recover three quarters' rent in respect of No. 80, Grosvenor-street, held on a long lease at £300 yearly rent by the defendant, a surgeon. One quarter's rent was admitted to be due, and paid into Court; as to the others, it was claimed no rent was due by reason of an interference with the defendant's enjoyment of the premises. It appeared that at the Grosvenor Gallery the London Electric Supply Corporation had carried on their business, and had established their works on the premises abutting on the defendant's tenement at the back. Of these premises the plaintiff was the landlord; and when the defendant made serious complaints of the noise created by the steam engines and the dynamos, an agreement was come to that no rent should be due from the defendant so long as any interference with his enjoyment existed by reason of the machinery of the Corporation.

Digitized by Google

Shortly after, in 1890, the engines and the dynamos were removed to Deptford. No further complaint was made of any noise until January, 1892, when complaint of noises coming from the same premises, but of a different character, was made; it was alleged that they continued for six months, and that no rent was due during that period. In answer to this, it was said that, as to part of the noise complained of, a "humming" noise, it proceeded from the "transformers," which had been there throughout the whole period without any complaint since 1890. As to the other part, the "beating" noise, that did not proceed from the premises as to which the agreement had been made, and could not be raised as a defence for the non-payment of rent, while, further, the noise was from a meter, and was of a very harmless kind, much like the sound of a clock.

Mr. Dickens, Q.C., and Mr. Willes Chitty were for the plaintiff; Mr. Winch, Q.C., and Mr. Scrutton for the defendant.

The onus being upon the defendant to establish the existence and the causes of these alleged noises, Mr. Winch, Q.C., opened the case, and examined Mr. Cowper. The defendant said all the nuisance was caused to the back rooms of his house—the kitchen, consulting-room, drawing-room, and his own bed-room. The engines had made "night hideous"; after their removal no further sounds were noticed until the end of 1891, and then two sounds arose which were most objectionable—an intermittent "humming" sound, like a threshing-machine at work next door, and a continuous beating sound. The humming sound abated in May, 1892, and so did the beating sound later on.

Mrs. Cowper, defendant's wife, said the nuisance had driven her from the house, and she had hardly been there at all during the continuance of it. Defendant's daughter and a visitor at their house also described the noises and their unpleasant effect. They made that side of the house uninhabitable.

Evidence was called on the plaintiff's side to show that the only transformers on the premises in question were in the basement, 20ft. below the defendant's basement. There were two there of about two tons weight between February, 1891, and May, 1892; but the heavy transformers of modern construction made less noise than the older and smaller. They did make a humming noise, but not at all a loud noise. Whatever noise they did make had been going on continuously and without any change from February, 1891, until May, 1892, but no complaint whatever was made during 1891 There was no noise that could disturb the defendant.

A meter was produced which was said to be the source of the beating sound complained of, and a current was passed through it; the sound which proceeded was like that of a clock.

After Mr. DICKENS and Mr. WINCH had addressed the jury,

His LORDSHIP said the only question for them was under the agreement. Considering the circumstances and the parties, had there been "any interference" substantially with the defendant's enjoyment? If there had been, the bargain was "no rent." The "interference" must come from the "transformers" in the basement, as the agreement only extended to them.

The jury brought in a verdict for the defendant, for whom judgment was given, with costs.

Loveland v. The Gas Light and Coke Company.

The case was tried in the Lord Mayor's Court in February last, by the Recorder and a special jury, and the plaintiff obtained a verdict, with £40 damages. On Tuesday last week it was sought to set aside the verdict, on the ground that there was no evidence of negligence. The case was tried before Justices Charles and Vaughan Williams. Mr. M'Intyre appeared for the plaintiff; Mr. Bigham, Q.C., and Mr. Morten represented the Company.

Mr. BIGHAM, in opening the case for the appellants, said the question for their Lordships to decide was whether there was any evidence to go to the jury. Most of the facts were admitted, but there was a dispute as to what was the real cause of the explosion. It took place in Great Tower-street. Harp-lane ran north and south, and Great Tower-street east and west. On the right and left of Harp-lane, where it entered Great Tower-street, were two electric-light boxes. These boxes were not air-tight, but were more or less water-tight. On October 14th last the defendant Company's men were working to the east of the box where the accident happened, using picks for the purpose of taking up the concrete, in order to get at some leaky gas-pipes; and at nine o'clock at night there was an explosion of gas, which had in some way gathered in the box. The explosion was of such force that the lid of the box was smashed to pieces, and the pressure of air forced up the lid of the other box, on which the plaintiff was standing. The first point of the other side was that there was a negligence of commission in improperly laying the gas-pipes; and the second, that there was negligence of omission in not finding out the leakage sooner. The third head suggested that the men in using their picks had caused sparks, which had ignited the mixture of gas and air, and thus brought about the explosion. There might be evidence of negligence in the present case if the Gas Company had had opportunities of finding out the escape and had not used reasonable means to do so. The evidence of Joseph Ansell, the housekeeper at 21, Great Tower-street (the City Meters' Office), was that for about a week before October 14th they had noticed a very strong smell of gas in the house. Ansell said he had made a complaint to his superiors; but that had not reached the Gas Company, who had never heard of it until the afternoon of the day when the explosion happened. Another witness named Rayden, a clerk in the same office, said he had noticed the smell of gas for twelve months, and that it was sometimes so bad that he could hardly bear to be in the place. The question was whether there were any means by which the Gas Company could have discovered the leak. They could not go inside houses smelling about for a possible escape of gas. The Company sent round men called leak-detectors, to examine the syphons and water-boxes; but they could not be periodically digging up the streets, in order to look for leaks of which there might be no evidence whatever. Mr. Foulger, in his evidence, said that, in his opinion, the explosion was caused by the gas going up the electric column, and being ignited at the light itself.

Their Lordships then delivered judgment, without calling upon counsel for the plaintiff.

Justice CHARLES said in this case they were invited to say that there was no evidence of negligence on the part of the defendants to go to the jury. It was proved by the evidence of persons resident in, or employed at, No. 21, Great Tower-street, that for a long period prior to October 14th there had been a smell of gas in that house. Two entries made by the defendants themselves as to the state of the main opposite No. 21 had been put in, which disclosed that there were two leaky joints in the main. There could be no doubt, having regard to the evidence, that those were leaky joints of long standing. In that state of things, the defendant Company asked the Recorder to stop the case, on the ground that the plaintiff had not proved negligence on their part. The Recorder very properly declined to stop the case: and thereupon the defendants took upon themselves the onus of showing that the state of things in the main, and the existence of those leaky joints, could not by reasonable care have been known to them. He was of opinion that they had signally failed to prove it. On the contrary, their evidence supplemented to a considerable extent the evidence offered on the part of the plaintiff, for it turned out from the statements of the defendants' witnesses that the Company were in the habit of taking steps to see if their mains were in order. They employed men called leak-detectors and also persons called pumpers. If these persons did their duty they would go to that place weekly; and they would, therefore, have been there within a few days of the time that the accident happened. They were not called as witnesses for the defence, and all the defendants had proved was that no report had been received from any of their leak-detectors with regard to the state of those joints. The evidence called on the part of the defendants proved that the leaks were old ones. The ground had fallen away, and one leak was a very bad one. Looking at that evidence, he was of opinion that the defendants had failed to discharge the onus thrown upon them to show that they had exercised reasonable care. They had not thought fit to produce any evidence from the persons whose duty it was to make periodical inspections. The jury were amply justified in finding that this leak was one which might have been discovered by the Company by the exercise of reasonable care; and the verdict would therefore stand.

Justice WILLIAMS said he was of the same opinion.

Mr. MORTEN said the judgment was one of great importance to the Gas Company, and he therefore asked for leave to appeal.

Justice CHARLES said the Court could not accede to the application.

Birmingham Telegraph Factory (Limited).

At the Birmingham County Court last week, before Judge Chalmers, an application was made for the compulsory winding-up of this Company by Messrs. H. Alabaster, Gatehouse, and Co., London. There were 14 shareholders in the Company, of whom Fowler, Lancaster, and Co. (Limited) were the holders of 400 shares out of 5,000 originally allotted to them as vendors to the Company of property at a price alleged to have been considerably in excess of its value. A meeting of the shareholders was held in February last, when it was resolved to wind up the concern in voluntary liquidation, and Mr. James Rhodes was appointed liquidator. The statement of affairs showed liabilities £7,733, and assets £5,784, but this did not include any liability on account of the shares. Of the 707 shares stated to have been issued by the Company, 307, or thereabouts, had not been paid for. Some of the shareholders and Directors of the Company were also shareholders and Directors of Fowler, Lancaster, and Co. (Limited), and were the holders in their own names of a large number of the shares in the Telegraph Factory, which had not been paid for in cash.

Mr. ALFRED YOUNG, for the petitioners, said that they were creditors of the Factory to the amount of £174 and they were anxious for an investigation by an official liquidator, not only as regarded the doings of the Company, but also in respect of Fowler, Lancaster, and Co. Limited), who were the promoters of the Company, and whose affairs were also in voluntary liquidation. The Telegraph Factory had a capital of £50,000, and the consideration to be paid to the Fowler-Lancaster Company was £5,000, of which £1,000 was to be paid in cash and £4,000 in shares fully-paid up. In the voluntary liquidation of the Factory the Fowler-Lancaster Company claimed to have advanced £6,000 in and about the financing of the Factory Company, for which they had debentures for £3,000 on the assets of the Factory Company, and £3,000 in fully-paid up shares, regarding which latter there had been no payment made whatever. They had been allotted to Lieutentant-General Sir Andrew Clarke, Mr. J. F. Albright, Major Roe, and Messrs. E. W. Lancaster, A. Mason, and G. Fowler.

After some discussion, the JUDGE said that the question turned upon the liability of the holders of the £3,000 of shares, and he suggested that this question of their liability should be raised and decided.

Eventually, the matter was adjourned till next bankruptcy day for Fowler and Lancaster to file further affidavits, and for them to attend the Court for examination. All the books are to be open to the inspection of the petitioners.

Re Fowler, Lancaster and Co.

This was the petition of a creditor for £159 for the winding up of the Company. Mr. Justice Vaughan Williams had on a previous occasion expressed dissatisfaction at the state of the evidence filed on behalf of the respondents, who were the Company and the debenture-holders, and gave them an opportunity of filing further evidence.

Mr. HART on Wednesday stated that the further evidence had been filed, but this had not been cross-examined upon, as it consisted solely of

Digitized by Google

the evidence of the liquidator, who got his knowledge from the books and papers of the Company, and of Mr. Fowler, which did not touch upon the matter upon which the creditor based his claim. In respect of £109 of his client's claim, a bill was given and dishonoured. The petition was opposed on two grounds—the first, that nothing was to be gained by a winding up order, because the debentures covered the whole of the assets of the Company, and the second, that there was already a voluntary winding up by which unsecured creditors would not be prejudiced. He asked that his lordship would hold that the receiver had not taken a too sanguine view of the value of the assets he was able to realise, and make a compulsory order.

The hearing was subsequently adjourned to Thursday (yesterday), when it was stated that an arrangement had been arrived at between the counsel, and his lordship acceded to a request that the matter might again stand over for a time.

Electric Arms and Ammunition Syndicate (Limited) v. Lucas.

In the Lord Mayor's Court last week, before the Recorder, the plaintiff Company sued the defendant, a civil engineer at Hammersmith, to recover £42, being calls on shares in the plaintiff Company. The defendant declined to pay on the ground that there had been misrepresentations in the prospectus which was issued by the plaintiffs. The defendant also claimed to have his name erased from the register, and counterclaimed £100, being the amount he had already subscribed on his shares. The syndicate was formed for the purpose of making and vending firearms in which electricity was used as the means of exploding the cartridges and it was claimed for the invention that it could be adapted to all existing kinds of firearms and fowling pieces. The secretary of the Company was called and explained the operations which had been carried on by the Company, including a trial of the weapons at Bisley, and also negociations with the War Office with the object of getting the authorities to adopt the invention. The defendant in his evidence, said he complained that it was not true, as alleged in the prospectus, that negociations were proceeding with foreign governments to induce them to take the weapons. Neither was it true that the invention was perfected, but he had no evidence to produce in support of that view. Upon this the Recorder directed the jury that there was no case for the defendant and a verdict was given for the plaintiffs, with costs on the higher scale.

Electrical Supplies and Fittings Company (Limited).

Mr. Justice Vaughan Williams on Wednesday made an order continuing the voluntary winding-up of this Company under the supervision of the Court.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *May* 5, 1893.

The Effect of the Incandescent Lamp Decision.—The decision of Judge Hallett in favour of the Columbia Incandescent Company of St. Louis against the Edison interests is having a stimulating effect on the electrical business in general, and especially upon the incandescent lamp industry While this decision does not settle the legal fight between the General Electric Company and the outside manufacturers, it certainly has had the effect of breaking the so-called monopoly of that Company. Pending the final hearing, which will consume perhaps a year or two years time, the Columbia Incandescent Lamp Company and a number of other companies can unquestionably pursue the manufacture of incandescent lamps. Already several companies have resumed their business, which had been suspended by the action of the General Electric Company, and incandescent lamps of different makes can now be obtained in the open market, and it seems probable that this state of affairs will continue until the expiration of the Edison patent.

The Opening of the Chicago Exhibition.—On May 1st the Chicago Exhibition was opened by the President of the United States with appropriate ceremonies. While the appointed time does not find the Exhibition in anything like a completed state, there is every prospect of the major part of the exhibits being in good condition within the next two or three weeks. The electrical display, which will, perhaps, be the most attractive feature, both from the standpoint of the general public and the engineer, is further advanced than most of the others, but the Electrical Building is still in in a very unfinished state. The Intra-mural Railway, which was opened to the public last week, marks an important step in electric traction in this country, as it is really the first elevated electrical railway of any pretentions that has been constructed on this continent. The construction of the motors, and their attachment to the cars, the trolley, the feeder and working circuits, are all of particular interest to electrical and street-railway men, but the great 2,000 horse-power generator, in the power station, will probably excite more interest than any other feature. The company constructing the road secured the contract on a bid of 25 per cent. of the gross receipts and a ten cent fare.

CORRESPONDENCE.

COOKING BY ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your attention may have been called to a note in a contemporary interested in gas lighting, criticising Mr. Crompton's lecture at Hove, and making a comparison between the cost of electric heating and the cost of coal. It is stated for purposes of comparison that, taking electricity at 5d. per unit, the price of coal should be £7. 7s. 1d. per ton. I should be glad if you would allow me an opportunity of pointing out to your readers that Mr. Crompton, in his lecture, told his audience that electrical heating, although it appeared costly calculated in the above manner, is not so in reality when the heating has to be applied for short periods of time, and only at the points where it is actually required. A large number of cooking operations come under this head.

The theoretical value in heat units of a ton of coal, and its practical value when burned in the average stove, are two different things. Probably about 50 per cent. of the heat passes up the chimney in the form of products of combustion, and this loss alone would double the price of coal when compared with electricity. For short operations coal is expensive, for a fire is of little use during the first half hour of its existence; and when the fire is done with, a considerable amount of heat is lost in its expiring embers. With electricity the matter is very different, the full heating effect of the current is experienced almost instantaneously, and owing to the fact that there is no combustion, the heated conductor may be enclosed within, or attached to, the apparatus in use. Thus, practically, the whole of the heating effect is utilised, without waste in starting or stopping, for immediately the work is done the current is switched off, and no loss is experienced. From the above facts I consider a fair comparison of electricity with coal would be as two to one. This is for some cooking operations, but not all. Thus, the electric oven completely turns the tables on its opponents. The oven, which is entirely enclosed, is heated, say, to 400 degrees in 15 to 20 minutes at double the cost of gas or coal, but as there are no means for the heated air to escape, the electricity may be entirely turned off when this heat is attained. But for the fact that there must always be some slight loss of heat through the walls of the oven, no more heating would be required. By allowing, however, 25 per cent. of the original current to pass through the oven, the full heat may be maintained, and cooking operations carried on indefinitely. Therefore, if electricity costs twice as much as gas or coal to heat up the oven in the first instance, it only costs half as much to keep it going.

I have tried the experiment of heating up an electric oven to 400°F., and after shutting off all current, taken tests for the next two hours. At the end of that time the temperature was still 250 deg., which is sufficient for many cooking operations originally commenced at a higher temperature. The cooking carried on during the last two hours would not have cost a single cent; in fact, the electric oven acts like a baker's oven, which being heated early in the morning, has to cook afterwards by means of the heat retained.

It is a very simple matter to calculate the cost of carrying out small cooking operations. For instance, taking the usual pressure of 100 volts, a unit will give us 10 amperes for one hour. For heating purposes electricity is supplied by many companies at a lower rate than for lighting, owing, no doubt, to the fact that cooking is mostly carried out during the day. Taking the price at 5d. we get the following:—A large size electric toaster will toast perfectly two rounds of bread in one minute. The toaster takes 7 amperes at 100 volts. If this apparatus is used for one hour it will cost seven-tenths of 5d.;

Digitized by Google

i.e., 3½d. At the rapid rate, however, at which the toaster will work, it will probably not be required more than ten minutes at a time, and the current for this would cost one-sixth of 3½d., or a fraction over ½d. Three minutes, however, must be allowed for the toaster to get to its full heat before using, and, therefore, we must add one-twentieth of 3½d. We may very well say that the toaster will work in the most efficient and satisfactory manner for about ten minutes at the cost of less than 1d.

The electric griller will grill four chops or six cutlets in ten or twelve minutes, using 6 amperes. Add to the time taken in actual cooking three minutes to heat up the plate in the first instance, and we find that current will be required for about fifteen minutes at 6 amperes. The cost of this would be about 1½d. It is convenient to remember that at 5d. a unit we are paying ½d. per ampere per hour. To boil a quart of water requires about 3½ amperes for ten minutes, but if we allow a quarter of an hour for this operation, the cost is about ½d. It is quite a question whether the usual spirit stove would be as cheap.

If we add to the above the many great advantages and savings due to the absence of waste heat, smell, smoke, and dirt, the cost of electric heating for many cooking purposes is certainly very little, if at all, in excess of coal. I doubt very much, when all the bye savings are taken into consideration, whether it is dearer at all.

The above figures are taken on the assumption that electricity is supplied at the price of 5d. per unit. It may be obtained, however, at 4d. per unit at the present time in the City for heating purposes, and in other parts of the country it is as low, and at St. Pancras it is charged at 3d. These prices make the comparison still more favourable. The convenience of being able to switch on or off the heating power at will, and to carry on the cooking operations in any part of the kitchen without reference to chimney accommodation will certainly bring electric cooking into favour.

Large numbers of experts have seen the Crompton electric cooking apparatus, and without exception they have declared in favour of its use. The only point which seems to cause them any doubt is the question of safety, but this they soon see is only a "bogey" raised by our opponents. There is absolutely no more danger to life or limb in using electric cooking apparatus than in the use of the ordinary incandescent lamps, for all are worked with the same pressure.

Apologising for the length of this letter.—Yours, &c.,

London, E.C., May 16, 1893. H. J. DOWSING.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

The 1893 Edition of "THE ELECTRICIAN" Electrical Trades Directory and Handbook is NOW READY. This useful book contains over 1,000 pages, and several new and handy features have been added. Price 7s. 6d., post free 8s. 3d.; abroad 8s. 10d. *Comparison with any similar electrical publication is specially invited.*

TENDERS INVITED.—The Vestry of St. John, Hampstead, invites tenders for the construction, supply and laying down of plant and mains for the electric-light supply of the parish, in accordance with plans, &c., which can be obtained of Mr. A. H. Preece, of 39, Victoria-street, S.W. Some further particulars are given in our advertisement columns, and the tenders have to be delivered to Mr. Thomas Bridger, Vestry Clerk, by 4 p.m. on Thursday, June 8th.

——— The South Indian Railway Company (Limited) will receive tenders for the supply of general stores, including iron, metals, and telegraph stores until the 30th inst.

——— *Extension of Time.*—Owing to the time originally fixed for sending in tenders for the electric lighting of Clonmel, Ireland, being too short for the preparation of the necessary estimates, it has been decided to extend the time for sending in tenders from May 25th to June 25th next.

TENDERS ACCEPTED.—As was anticipated, the Corporation of Leicester have accepted the tender of the Brush Electrical Engineering Company (Limited) for providing a high-tension electric light installation in a limited area in the centre of the town, the amount of the tender being £27,587.

TENDERS ACCEPTED.—The Town Council of Dewsbury have accepted the following tenders for contracts in connection with their electric lighting scheme, subject to the recommendations of the Lighting and Water Committee, set out on the next page. Messrs. Crompton and Co. (Limited), London, engines, dynamos, accumulator switch boards, &c.; Messrs. Siemens Bros. and Co. (Limited), London, mains (including arc lighting); Messrs. J. and J. Horsfield, Dewsbury, boilers.

——— The Town Council of Hanley have accepted the tender of Mr. Thomas Cass for fitting up with his mechanical coking stoker three boilers at the Council's electricity works for the amount of £270.

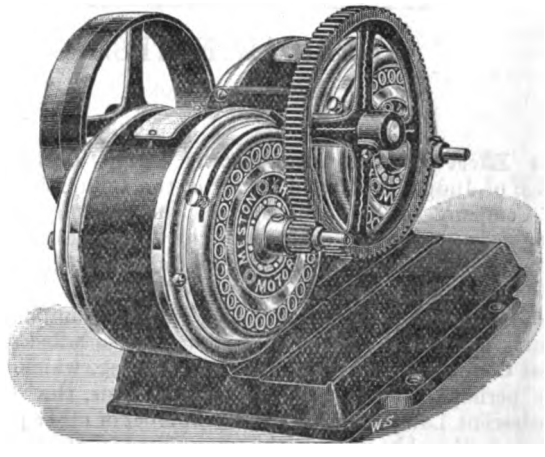
——— The following tenders were sent in for the supply of electric-light fittings for the Horseshoe Tavern, Tottenham Court-road, W.C.:—Messrs. Laing, Wharton, and Down, £354; Messrs. Verity and Co., £351; Messrs. Strode and Co., £301; J. Dodson, £287; Messrs. Vaughan and Brown, £275—the latter tender being accepted.

——— At their last meeting the Bristol Town Council adopted the report of the Electrical Committee, referred to in last week's *Electrician*, recommending the acceptance of tenders for the supply of apparatus at the central and sub-stations.

MESSRS. DRAKE AND GORHAM.—This firm have secured the contract for lighting the new offices at King's Cross for the Great Northern Railway. The installation will consist of between 600 and 700 incandescents. The consulting engineer is Mr. A. H. Preece.

BANKRUPTCY.—On Wednesday, in the Court of Bankruptcy, before Mr. Registrar Giffard, a scheme of arrangement was approved under the failure of C. J. Allport, an electrical engineer, and son of the late Sir James Allport, formerly chairman of the Midland Railway. The statement of affairs shows liabilities to the amount of £14,880, and the scheme provides for payment of the creditors in full.——Creditors of James Collins, lately carrying on business as an electrical engineer, at 80, Church-road, Hove, Sussex, must send in proofs, by the 30th inst., to Mr. R. J. Ward, 7, Pavilion-buildings, Brighton.

NEW SLOW-SPEED ALTERNATING-CURRENT MOTOR.—We give below an illustration of a new alternate-current motor adapted for



small power purposes which is being placed on the market by Messrs. Shippey Brothers (Limited), on behalf of the Emerson Electric Company, and are being supplied in two windings for working on both 50 and 100-volt currents. It will be observed that two motors are mounted on one base and geared to a single countershaft, thus giving twice the power of the single motors. The countershaft is geared to the motor-shaft, which gives the driving-wheel a velocity of 200 to 280 revolutions per minute, the motors running at from 2,000 to 2,500 per minute. We are informed that these motors are self-starting, also self-regulating and reversible, and will automatically synchronise at any speed required, according to the periodicity of the circuit. For working sewing machines, for instance, they can be run to produce from 30 stiches per minute up to 1,500 or over, if required. The armature is made of special laminated iron, but has no winding. The motor has self-oiling bearings, and all the working parts are entirely enclosed.

FIRE.—The premises of Messrs. Lea, Sons, and Co., electrical engineers, Chester-street, Shrewsbury, were seriously damaged by fire on Monday last.

CENTRAL STATION CONTRACTS.—The Scottish House-to-House Electric Supply Company have placed a contract with the Brush Company for the complete equipment of a supply station at Coatbridge on the Mordey-Victoria alternating-current system, the

Digitized by Google

generators to be driven by Griffin gas engines and Dowson gas. The Brush Company have also received an order from the Great Northern Railway Company for the supply of arc lamps and accessories for their central station at Holloway.

CHANGE OF ADDRESS.—Messrs. Crosier, Mills, and Co. have removed from 9, Queen-street, to 58, Collingwood-street, Newcastle-on-Tyne.

ELECTRIC LAUNCHES.—Messrs. Drake and Gorham, who inform us they were practically connected with the manufacture and design of the first launches shown on the River Thames, are again devoting their attention to this branch. Two electric launches under the firm's control will shortly be ready for running on the Thames.

MOTORS.—With a view of increasing the day load of central stations, a special section of the thirtieth International Machinery Exhibition at Breslau will be devoted to electric motors. The Exhibition will be open on June 15th, 16th, and 17th. Current will be supplied free to exhibitors. Further particulars may be obtained from Otto Höffer, secretary to the Exhibition, 28, Kreustrasse, Breslau.

BIRMINGHAM.—Before the City Council Mr. Alderman Pollock last week presented the report of the Gas Committee, and deplored the fact that a considerable diminution in the receipts had resulted from the past year's working. No doubt the Committee could have made up for the decrease by raising the price of gas 2d. per 1,000 cubic feet, but they did not wish to adopt that course, as such action would have stimulated the use of the electric light in offices and warehouses, and also in the yards and large works of the district. He anticipated a speedy improvement and an increased consumption of "the cheerful, bright, warmth-giving gas!"

CLONMEL (IRELAND).—Active steps are being taken by the Municipality for obtaining a Provisional Order to light the borough by electricity.

DEWSBURY.—On the 25th ult., Mr. W. H. Preece and Mr. A. H. Preece, attended before the Town Council with a report on the tenders for the central station plant, and at the same meeting a deputation was appointed to wait upon Mr. M. Oldroyd, M.P., to induce him to obtain the electric light for the Spinkwell Mills from the Corporation instead of establishing an isolated plant. On May 2nd Mr. Oldroyd informed the deputation that it was impossible for the mills to be supplied with current from the Corporation's mains, as the installation which his firm were putting in had advanced to near completion, but that in the event of future extension the matter would be considered. With regard to the lighting tenders the Lighting and Water Committee recommended:—(1.) That the provision for lighting with arc lamps the public streets in the compulsory area should be dispensed with, except in so far as the laying down of the necessary tubes for the mains at some future time; this was estimated to save in first cost £2,500. (2.) That the system of electric lighting be a continuous-current low-tension system. (3.) That the engines to be employed be Willans' high-speed direct-acting engines. (4.) That, subject to settlement of details of price between Mr. Preece and the contractors, and to further consideration as to the employment, or otherwise, of batteries or accumulators, and other small matters of detail, the list of tenders as set out on page 78 be accepted. It was also decided to obtain the sanction of the Local Government Board for the borrowing of £25,000 for electric-lighting purposes. It was resolved to approve the plans for the central station. The recommendations of the Committee were adopted by the Council.

EDINBURGH.—The large installation of the electric light at the Caledonian Railway Station was switched on last week, and proved highly satisfactory. In all, 50 arc lamps and about 1,000 incandescents are included in the work, which has been supplied by the Brush Company. The work has been carried out by the Caledonian Company's staff, under the direction of Mr. A. S. Dunn. ——On Tuesday, the Town Council discussed a motion by Bailie Walcot disapproving the decision of a previous meeting of the Council, when it was agreed to retain in the hands of the Corporation the electric lighting of the compulsory area. The Lord Provost, in moving the adoption of the minutes of the previous meeting, pointed out that by passing the amendment they would be deviating from the policy observed by all the large towns in the kingdom. The minutes were subsequently adopted.

GALASHIELS.—The Town Council have resolved not to oppose the application for a Provisional Order by the Company which is to be formed for introducing the electric light for private consumption into Galashiels.

HASTINGS.—The Public Lighting Committee have recommended the installation of the electric light in the Town Hall and Brassey Institute at the total estimated cost of £105. Notice was also given to the local gas company that gas lighting would be discontinued between the Fish Market and the West Marina from October 1st next.

HICKLETON.—The Hickleton Main Colliery Company are sinking a new shaft, and Messrs. Tasker, of Sheffield, have supplied a considerable installation of the electric light, which is ultimately to be in general use in the mine.

HOVE.—A discussion took place at the last meeting of the Commissioners on the subject of the electric lighting of the Town Hall and offices. It appears that 15 tenders and schemes were received in answer to the Commissioners' advertisements, and the tenders of Messrs. Crompton and Co. (Limited), and Messrs. Strode and Co. were recommended by the expert whom the Lighting Committee consulted. The tenders were marked A and B, and amounted to £638 and £725. 6s. respectively from Messrs. Crompton and Co. (Limited), and £905. 3s. 6d. and £454. 17s. 3d. from Messrs. Strode and Co., showing the small difference of £2. 13s. 3d. in the totals of the two tenders. After some discussion the proposal of the Committee to apply to the Local Government Board for sanction to borrow the necessary money was approved. A report of the Electric Light Committee, which also came under discussion at the same meeting, states that over five miles of streets have been opened for electric-light mains, leaving about two miles yet to be completed in the compulsory area, and outside this area a further two miles have been completed.

KILLIN (N.B.).—The proposal for lighting the town by the electric light, and utilising the water power which is available, is receiving considerable support.

LLANGOLLEN.—At the last meeting of the Local Board Mr. J. P Davies explained to the members the system of electric lighting which is proposed for the town, and moved that steps be taken to carry out the scheme. The matter was referred to a Committee.

MANCHESTER.—At the last meeting of the City Council the estimates for lighting the public free libraries by the electric light were passed, the opinion being expressed that the light would be an advantage to the readers, and would not be extravagant in cost, when the pernicious results of the gas lighting upon the bindings of the books were taken consideration.

NEWPORT (MON.).—In reference to the report of Prof. Robinson and his electric lighting scheme, the Brush Company have offered to submit, free of charge, a scheme and tender adapting their system to the requirements of the town; and the Lighting Committee of the Town Council have accepted this, on condition that the Corporation is not committed to any expense in the matter.

NEW SOUTH WALES.—The cost of the plant for the production of the electric light used at the General Post Office at Sydney, including that connected with the external lighting, was for 1892, £2,543. 16s. 5d.

PRESENTATION.—Mr. J. D. Miller, M.I.E.E., who has been appointed from the Dundee district of the National Telephone Company to Edinburgh, was presented with a handsome timepiece and vase, as a token of esteem, by the members of the Dundee staff. The presentation was made by Mr. Gilmour, the Company's representative in Aberdeen.

ST. PANCRAS.—A report has been received by the Vestry from the Joint Committee appointed to consider the question of combining the destruction of refuse with the production of electricity, and, without recommending the Vestry at the present stage to commit themselves to all the details in the engineer's report, the Committee expressed their approval that the principle should be adopted and that steps should be at once taken for carrying out the scheme.

SHANGHAI.—The New Shanghai Electric Company have undertaken to light the new Central Police Station by electricity at 6d. per unit, with a small addition for transformer rent charge.

SHREWSBURY.—The County Council have been notified of the intention of the local Gas Company to increase the charge for gas for street lamps by 4s. per annum. At the last meeting it was suggested that steps be taken to light the town by electricity, and the Council approved that the matter should be taken into consideration.

SOUTHAMPTON.—The Local Government Board have given their sanction for the borrowing of £400 for the lighting of the free library by electricity.

WEST CALDER.—The Local Committee has laid before the West Calder Co-operative Society a proposal by which they agree to incur the expense of working arc lamps throughout the streets, if the Society will supply the electric current free of charge from their installation. The Society have agreed to this.

WEST HAM.—The Librarian has presented a report to the Town Council of West Ham, in which reference is made to the methods of lighting the principal public libraries throughout the country. He strongly advises the use of the electric light, and if the decision of the Council is favourable to this proposal, that steps should be at once taken to put the work in hand, before the plastering and decorating work is complete.

PATENT RECORD

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

May 4, 1893.

8,925. H. L. LECONTE and L. A. MEYER. London. Improved electrical time transmitter and alarm.

8,952. F. W. ELLERMANN. London. Improvements in electric accumulators.*

8,958. G. G. B. RIGOLA. London. Improved apparatus for applying electricity to the body.

May 5, 1893.

8,969. G. J. SOMERVILLE and R. MCLEAN. Manchester. Improvements in switching arrangements at telephone exchanges and subscribers' instruments.

May 6, 1893.

9,090. W. S. BOULT and C. R. BOULT. London. Improvements in or relating to the parallel working of alternating-current generators specially applicable in connection with gas and similar engines.

9,092. W. S. BOULT and C. R. BOULT. London. Improvements or in relating to the "capping" of electric incandescent or glow lamps.

9 126. J. JEYES. Plumstead. An electric arc lamp, improved method for maintaining a uniform arc.

May 8, 1893.

9,136. E. J. PATERSON and J. FOXCROFT. Dalston. An improved clutching device for use in electric arc lamps.

9,149. C. A. RANDALL. London. Improvements in telephony.

9,171. H. DE PHILLIPS. Dover. Improvements in electrically-illuminated gunsights for use at night.

9,184. E. C. DE SEGUNDO. London. An improvement in arc electric lamps.

9,204. H. E. HARRISON. London. Improvements in electrical measuring and recording instruments.

May 9, 1893.

9,262. O. ERICSSON. Birmingham. Electric meters.

9,281. R. H. GOULD. London. New apparatus for counting telephonic messages.

9,295. T. CRANEY. London. An improved electrolytic apparatus.*

9,296. T. CRANEY. London. Improvements in apparatus for the electrolysis of salt.*

9,297. T. CRANEY. London. An improved electrolytic apparatus.*

9,302. W. Q. PREWITT. London. Improvements in contacts for underground electric railways.*

9,304. A. J. BOULT. London. Improvements in electric lamps. (J. Waring, United States.)*

9,308. F. VOGEL. London. Improvements in machines for equalising electrical currents without a current inverter.

MAY 10, 1893.

9,358. G. BINSWANGER. London. Improvements in connections for electric lighting and like purposes.*

9,380. R. HADDAN. London. Improvements relating to automatic breaking of current circuit for electric lamps or other devices. (A. Reisinger, Germany).

9,397. C. R. GARRARD and T. W. BLUMFIELD. London. Improved means for taking or transmitting power from electro-motors.

May 11, 1893.

9,473. G. RUSSELL. London. An improved electrical device for curative purposes.

9,478. H. H. LAKE. London. Improvements in insulators for electric wires. (Hartmann and Braun, Germany).

9,479. R. CHAVARRIA-CONTARDO. London. Improvements in, or connected with turnstiles, and electric counters connected therewith.*

May 12, 1893.

9,486. W. GREENHALGH and S. W. CUTTRISS. Leeds. Improvements in stands for electro-motors for dental and other purposes.

9,529. J. A. MCMULLEN. London. Improvements in or relating to the distribution of electricity for electric lighting or other purposes.

9,552. F. PETZOLD. London. Improvements in or relating to microphones and telephones.

9,557. H. N. PRENTICE. London. Improvements in dynamo electric machines and electric motors.

May 13, 1893.

9,627, H. FARADAY. London. Improved means for supporting porcelain or other imitation candles on electric-light fittings.

COMPANIES' MEETINGS AND REPORTS.

West India and Panama Telegraph Company (Limited).

The thirty-second ordinary general meeting of this Company was held on Tuesday last at Winchester House, Old Broad-street, E.C., Mr. C. W. Earle presiding.

The SECRETARY (Mr. R. T. Brown) read the notice convening the meeting and the minutes of the previous meeting, the latter being signed by the Chairman as correctly entered.

The report of the Directors and statement of accounts were taken as read.

The CHAIRMAN: Gentlemen—It is almost exactly a year ago that it was my duty to refer to the first death which had occurred on the Board of this Company that was elected to manage its affairs in the year 1874, and now I have again the same painful duty to perform in reporting that another venerable member of our Board has been taken away. Sir James Anderson, whose death we mourn to-day, was so well known and so highly appreciated in the telegraphic world generally that it is unnecessary for me to say very much about him. Many of you know he first came into connection with telegraphic business by successfully laying the 1866 American cable, which made the first telegraphic communication between the old and new world. He was knighted by Her Majesty after the service of that important operation, and left the sea, on which he had spent the earlier years of his life, and took a very leading part in the establishment, management, and administration of the great submarine lines which followed upon the successful laying of the American cable. He was Managing Director of the Eastern Telegraph Company, Chairman of the Brazilian Submarine Company, and, in fact, there is hardly an important submarine telegraph enterprise with which Sir James was not connected. The great experience that he gained in the working of these different lines was of very great value to us on this Board. Besides these advantages, we had the satisfaction of being associated with a most liberal-minded, kind, and thoroughly honest gentleman. I should be very much surprised to hear that Sir James Anderson ever made a single enemy during his whole career. He was so kind and considerate to all that, in fact, I should not be disposed to think very well of the man who said that he was Sir James Anderson's enemy. I am sure that the various staffs that he controlled will feel his loss as much as the Boards of which he was so distinguished a member.

The principal feature of the accounts which we present to-day is that there is an increased revenue of £2,217, and a decreased expenditure of £141. This small decrease in expenditure does not quite measure the real decrease, because in the accounts of the corresponding period of last year we had charged a sum of £2,119 to the reserve fund, as

Digitized by Google

some repairs were made which were really of so extensive a character as to constitute renewals in some portions of our system. Therefore, we may look on our accounts as showing an improvement of £4,000 over the corresponding period of the previous year. The items which make up the difference are to be found in abstract "C" of the accounts, which relates to the repairs of the system. This half-year our repairing bill is about £3,000 less than it was in the corresponding period of 1891. We used in the maintenance of our system 37 knots of cable, as against 78 knots; therein being the difference in the expenditure on that part of the business. In order to keep our reserve up to what we think it ought to be, we have decided to put £1,500 to that fund. Abstracts "A" and "B," I think, afford no subject for particular remark. There are slight variations in the items, sometimes increases and sometimes decreases, as compared with last year's accounts, and these are dependent mainly on the fluctuations of the staff and so on, and are not material. The traffic receipts show an increase of £2,065, but it must be borne in mind that these compare with a decrease of £7,350, which we had to report in the corresponding half of last year, owing to the reduced tariffs that we were compelled to initiate at that time. The increase this half-year may be attributed entirely to the improved conditions of the West India trade. Sugar, cocoa, and other staple articles in which the West Indies deal, have risen very much in value, and this has given a filip to telegraph business. Comparing this account to-day, and its increase of £2,065, as against a decrease of £7,350 last half-year, we get to the figure £5,285, compared with what we were making in the corresponding half of the previous year, the one in which we made the reduced tariffs, and that is, I presume, the measure of the loss. Yet we are told that if we reduced tariffs we should have a very much better business. Reductions have been tried in all parts of the world, and I think I am right in saying that wherever they have been tried there has been a considerable loss; and especially in countries like the West Indies, where the bulk of the inhabitants are not of the Anglo-Saxon or European race, the traffic has never increased in proportion to the decreased tariffs. It is rather disheartening to find that our subsidies have been reduced. The Colony of Trinidad, which gave us, for a term of ten years, £6,000 a year, has reduced the amount to £3,000 for one year. The Colony of St. Lucia has also reduced its subsidy from £800 to £500. That seems rather rough after we have given them such considerable reductions in the tariffs. In 1874, when we took office, the subsidy payable by Trinidad was £2,500 a year; but when the term of the subsidy, which had been guaranteed, lapsed, we made strong representations to the Colony of the necessity of allowing something more, and they liberally increased it to £6,000, or more than double the amount. The Colony is, perhaps, not very flourishing financially just now, and it has knocked off one-half of what it used to pay us. In the case of St. Lucia there was a subsidy of £500. We represented to the authorities there, as we did to Trinidad, that we wanted something more, and they increased the amount to £800; and now they have reverted to the original position. This is somewhat disappointing, but it is a matter over which we have no control. One of our ships was recently brought home for the purpose of having a new boiler put in, and that has been very successfully carried out. I may mention that our colleague, Mr. Holmes, had superintendence of the vessel while she was here, and was every day down at the docks, and the work done under his superintendence was admirably performed. Of course, we had a competent engineer to examine the boiler and see it put right, while Mr. Holmes conducted the other business. Gentlemen, that is about as much as I have to say to you to-day. But I shall be very glad to answer any questions which you may choose to put to me. I now move the following resolution:—

"Resolved, that the Directors' report and accounts to December 31, 1892, submitted to this meeting, be and the same are hereby received and adopted, and that, as recommended by the Board, dividends of 6s. per share on the first preference shares, of 6s. on the second preference shares, and of 6d. per share on the ordinary shares (the last free of income-tax) be and the same are hereby declared."

Mr. H. WEAVER seconded the resolution.

Mr. STANSFIELD said that it must be very gratifying to the Directors that they had received the unwavering support of the shareholders for so many years, during which they had had so many difficulties to contend with. What he rose particularly to ask was, what were they to regard as the maximum of the reserve fund.

Mr. BACON said that the only thing that struck him in reference to the working of the Company was the account under abstract "C." He noticed that their ships had been occupied but a very short time during the year, and he wished to ask the Board whether for the work required to be done one vessel would not be sufficient. It seemed to him that it would. If that were so, the shareholders would stand a better chance of an increased dividend. Their ordinary expenses, however, did not seem to be at all extravagant.

Mr. LUCK said that, as one of the ordinary long-suffering shareholders, a dividend of 6d. per share was not a large sum, especially as in his case he paid the full £5 per share for his holding, and the time had arrived when they should receive some consideration by a rigid economy.

Mr. GRIFFITH said that he was sure they all regretted the death of Sir James Anderson, who was undoubtedly a tower of strength in the telegraphic world, and it was unfortunate at this particular time that they should have lost a gentleman in whose experience and skill not only the shareholders but the public at large had so much confidence. As auditor of the Globe Company he had had to transact business with Sir James, and he could endorse everything which the Chairman had said with regard to the urbanity and skill of the deceased. He rather agreed with the remark of the previous speaker, that they ought to consider whether they could not effect greater economies, and especially in connection with the ships. He had been at the meeting of the Western and Brazilian the other day, and it was decided by that Company that one ship would effect all the repairs which would be required. If that Company could hold out such a hope to the shareholders, he trusted that similar encouragement might be afforded in the case of this Company. Although it was important that they should not adopt a cheese-paring policy, it was equally important that they should effect economies in the direction indicated. He also would suggest that they should put by £600 to the reserve fund by way of ship insurance. There was no reason why, if they insured their cables, they should not insure the ships. He did not see why they could not cut down the petty expenditure of £4,900 a year under abstract "C" by having only one vessel.

A SHAREHOLDER asked whether there were any other West India Governments that were likely to reduce their subsidies.

The CHAIRMAN said that they had no intimation of it at the present. With regard to the reserve fund they must be aware that it was accumulated for the purpose of renewing the cables when they became inoperative through old age, and as they had got 4,600 miles of cable, he did not think that with a reserve fund of £140,000, or £150,000, they should stop making contributions to it. As the Company went on, they must provide against depreciation, and he could not hold out any hopes of these contributions to the reserve fund being stopped. They did not amount to very much. Last year they took £2,000 from the reserve fund. The question raised as to the ships occupied the minds of the Directors constantly. They could not take the number of days that the ships were employed as an argument that the Company could do with one vessel, because very often both ships were at sea simultaneously—particularly in the West Indies where they were exposed to hurricanes, and where their ships had to be employed at the same time; and if the traffic were interfered with the Colonies stopped their subsidies. The shareholders, however, might depend upon it that the Directors would do their best to do away with one ship. They had ordered one of them home to be ready for emergencies, but he thought that they would not send it out immediately to the West Indies, in which case they would reduce the expenses considerably. They might depend upon it that the Directors were looking after the expenditure as closely as they could. He might remind Mr. Griffith that they did lose one ship and got fully paid for it out of the insurance.

The resolution was then carried.

On the motion of the CHAIRMAN, seconded by Mr. HOLMES, Mr. William Andrews, the retiring Director, was unanimously re-elected.

Mr. ANDREWS having briefly expressed his acknowledgment,

Mr. JOHN NEWTON proposed the re-appointment of the auditor of the Company, Mr. John G. Griffiths, F.C.A.

Mr. STANSFIELD seconded the motion.

Mr. GRIFFITH, while supporting the motion, gave it as his opinion that in these times when the public mind is shaken in regard to the soundness of public companies, it might be better to have two auditors instead of one. This suggestion, however, met with little approval, and the motion was carried.

An extraordinary general meeting was afterwards held for the purpose of considering, and, if thought fit, of passing a resolution to alter the minimum number of Directors of which the Board shall consist, in accordance with the Articles of Association.

The CHAIRMAN explained that on the death of Sir James Anderson it was found that they had not the minimum number of Directors prescribed by their Articles, and in order to save the Company the expense of having another member of the Board, they proposed to alter those Articles so as to avoid the necessity of electing another gentleman in the place of Sir James Anderson. It was purely a matter of economy, because the other members of the Directorate did not intend to appropriate the fees appertaining to the vacant seat. He concluded by moving the following resolution:—

"Resolved, that until a general meeting shall otherwise determine, the Board shall consist of any number, not less than four and not exceeding twelve Directors, and article 18 of the Company's Articles of Association shall be read and construed accordingly."

Mr. ANDREWS seconded the motion.

Mr. NEWTON said that he quite approved of the decision of the Board, especially in view of the fact that they were not to divide the fees amongst themselves.

Mr. GRIFFITH said that he could not support his friend, Mr. Newton, in this view, inasmuch as their business was becoming more complex, and it required all the ability they could command.

The motion was carried, there being only three dissentients.

Mr. NEWTON proposed a vote of thanks to the Chairman and the other Directors.

The motion, which was seconded by Mr. BACON, was cordially carried, and

The CHAIRMAN having expressed his thanks, the proceedings came to an end.

London Electric Supply Corporation (Limited).

The sixth ordinary general meeting of the shareholders of this Company was held at the offices on Wednesday, under the presidency of Mr. James Staats Forbes.

The SECRETARY and ACCOUNTANT (Mr. R. Stewart Bain) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, for the purpose of economy we decided to use our own Board-room for this meeting, but were rather alarmed that the space might prove insufficient. I am rather sorry to see that the space seems to be superfluous—a fact, however, from which I must assume that the report which the Directors have sent out has satisfied the minds of absent friends. We have insisted, during the last two or

Digitized by Google

three years, upon the engineer and the scientific gentlemen upon whom really, in the long run, the success of this and other similar companies must depend, pledging themselves from year to year as to the progress of the undertaking, not so much as a commerical undertaking as a scientific undertaking, to be some day or other capable of returning some adequate interest upon the capital expended on it. You know, I am afraid too well—we do on this side of the table—that our misfortunes have entirely rested upon the want of knowledge, which was pretty universal, as to this electrical possibility. You know the disasters we have had upon one or two occasions causing our whole business to be paralysed—stopped—for considerable periods, and how that affected the public mind naturally, because in this matter, as in every other thing, people will only attach themselves, for their comfort, convenience, or interest, to things that have been proved can be relied upon. We were in a very unfortunate position. We thought—every one thought—that this thing was started on a highly scientific and highly economic principle, and, of course, if it had acted perfectly, it would have been. It is owing to the very fact that the principle, however good it is, has more or less broken down in practice that we are in this position. Had it been accomodating enough to have broken down in such a manner as to have caused us to have been utterly hopeless of pulling it through, we must have put up with it, and have been content with the position; but it does undoubtedly contain within itself the possibility of being improved upon to the original idea. I am rather laying the ground now for what I shall have to administer to-day—the necessity of patience. In order that you may in a few figures realise the result of the irregularities and breakdowns that have from time to time affected us, I may tell you that we are now in this position. The fire at the Grosvenor occurred in November, 1890. At that time we had 38,272 lights connected, but that immediately dropped to 9,000, and these very speedily ceased altogether. We, therefore, had to begin business again, and I find that at the date of May, 1891, we had worked our way back to 23,000 lights. In 1892—during the year intervening, we had had some further troubles and interruptions, not of three or four months, but of only about as many days, with consequences almost as bad at the moment, for they shocked the public—we crept up from 1892 to 1893 to 55,900 lights. The result of that has been that all the various items involved in getting to the lamp have been slowly, with a great deal of difficulty, but with some degree of certainty, overcome; and the thing now really looks as if it were something like an efficient machine. Of course, if anything like the same progress is made in the two future years as we have had in the two past years, we shall be out of our trouble. One of the things to be borne in mind in this matter is that the working expenses are made up of two kinds of items. One item is, as it were, permanent, and has little or nothing to do with the production of current—that is to say, the quantity or the distribution of current—and which diminishes, therefore, exactly in the proportion that the consumption of current or the number of lamps lighted increases. The other item is what may be called the item connected immediately with consumption. Current is produced by coal chiefly, and there is a direct relation, after a certain number of thousands of units are got, between the cost of the unit up to any number of thousands or millions. That does not affect the fixed charges. The man working the machine costs you the same whether he is producing one million of units or five hundred thousand, and that goes through the maintenance of mains, the supervision, and other things which form a considerable percentage to the total outlay. Coming to the total outlay, the position is not at all satisfactorily relatively to the result; but the question is: Because the result has been disadvantageous owing to causes—however unfortunate, pretty intelligible—are we to throw up the sponge and retire from the business? That is not the temper of your advisers; nor do I think it will be yours when you see that, although the return for the year is not one upon which we can very much congratulate ourselves, still, it does present in itself the element of future hope, and, as far as patience goes, rational belief that the multiplication of customers will go on, and with the multiplication of customers the receipts will increase, whereas, for a large proportion of them, the expenses will remain stationary. This is the very unfortunate state of things—that our receipts in 1891 were £28,684, and that with two years of effort they should now be only £24,281, the expenses in both these years being almost exactly the same—£28,704 against £28,196. The intermediate year, which was a disastrous one for the reason I have told you—the serious breaks—showed even a worse result. Therefore, the point which I would advise shareholders upon, either those present or those who are obliged to depend upon printed matter for their information, is to study carefully these engineers' reports, because Directors of a commercial undertaking are not scientists usually, nor can they control the elements. They can exercise a certain amount of judgment and control, and they can exercise the most difficult and most precious of all gifts—discrimination—as to the value of opinions upon which they depend; and in matters of old history or old experience, it is not difficult at all to come easily to that conclusion; but in this electrical business it wants a very clever fellow indeed to discover whether the scientists are right or wrong till he himself has acquired some experience in the application of the scientific principle. During the past year we have had a good deal of work to get through; we started with something of a too magnificent idea. It was thought that the multiplication of power would be a great commercial power, and so it would be if all that power could always be fully occupied, but the gentlemen who were led away with that idea—the engineers and others—seemed to have forgotten that electric lighting begins with a low demand, culminates at a certain stage with a heavier demand, and then subsides into a low one; and if you start with machinery of one uniform type, calculated to do the maximum at the moment of highest demand, it is obvious that you must be working at great loss in the earlier and later stages. Therefore, what appears now to be the practical conclusion of a good many people is that it would have been wiser to have had a smaller unit. Instead of having two 625 H.P. dynamos and two 1,250 H.P. dynamos, to have started with two of 500 H.P., or some other more modest form of unit, would have been wiser. However, there it is, and we must make the best of the position. During the year we have spent a little money in starting a new unit of 300 H.P. We have one at work and one in course of construction, and it looks very much like having to abandon—for the present at all events, and perhaps for a long time to come—any idea of working with implements of such enormous cost, and so exceptional as 5,000-H.P. dynamos. You know that our plant consists, as I said, of two 625-H.P. dynamos and two of 1,250-H.P. These are all at work, but the 1,250 ones are not without drawbacks. First of all, as I think I had occasion to say before, if it so happened that you had to start with a 1,250-H.P. dynamo, it would be like cracking a nut with a steam hammer. A 300-H.P. dynamo does the work quite as well at starting, and the consumption of fuel is infinitely less. It all comes to this, apparently, therefore—whether these remodellings and experimental improvements are in the right direction. We believe that they are. We believe we have reason to adopt the report of the engineer, which you can read for yourselves, but which generally comes to this—that he has had occasion in several ways to modify various parts of the machines, and that he has got them into that position that they will do two things which it is greatly to our interest should be done. They can work with regularity and without continual breakdowns, and with much greater economy. We are suffering, no doubt, at present, and we shall suffer. It seems to be the penalty of shortcomings—I was going to say the penalty of misconduct, but I do not know whether that term could be applied to the errors of judgment in which this thing was started; though, at all events, we have lost our character with the public. Unfortunately, we also lost our turn. Everyone knows that when you want to get a particular seat in the pit at the theatre you get to the door first, and you then get in; but if you have half-a-dozen people before you, you will find the place occupied. That is what we did. We were not only late, but defective as regards our position; but the question is, do these figures that we have before us now form any encouragement to hang on on the idea that we shall retrieve our position? I think the whole thing is in the lamp; so many lamps so much money, receipts, and expenses. The greater the number of lamps the greater the receipts; the greater the number of lamps the less relative cost per lamp; and it all comes to that. When you have got 56,000, or twice 56,000, lamps going, what is the possible average you will get out per lamp? That is knowledge that we are getting. We started with contracts—so much per lamp per annum, for want of any other means. When we began this thing, and until almost recently, it was impossible to resort to any known method of measuring what we produced or sold. Happily for us, in the interim we have an effective meter, as far as a mechanical device of this delicate kind can be effective, and the character of our income has entirely changed in the last few years. A very slight portion of our income is derived from contracts now, and it all practically comes from meters, and we go by what is called the Board of Trade unit. I will not trouble you with a scientific description of the Board of Trade unit. That is a formula which has puzzled me and which must puzzle you. We were authorised to charge for that unit 7½d., and the success of this and of all similar undertakings turns upon how much you can produce it at. Hitherto we have been producing it at something more than the saleable price, which is very bad business; but it is material to bear in mind that the saleable price does depend on the multiplication of the lamps, and you will see at once what a different position we shall be in if, during the next two years, we double our number of lamps, because that will not be attended with anything like double the cost of production. In fact, it will be attended with a very small proportion of cost, and the great crucial test of this thing, as in many other great things, turns on very minute calculations of very minute quantities. If we can sell at 6d. a unit and produce at 4d., anyone can calculate how much so many hundreds or thousands of lamps in a year will give you, and it does not want such a very large number for us to get out of the slough of despond into comparative prosperity. I think I had better repeat myself, for one is obliged to get a sort of formula into the mind. We believe that the machinery we have now got at Deptford (barring the enormous dynamos, which it would be madness to go on with at present—and they must remain dead capital—but the three classes of dynamos I have described) will enable us to light certainly 90,000 lamps. For the sake of argument suppose the 90,000 should average the very modest sum of 10s. each, there is an income at once of £45,000. Our income this year was only £24,000, and the difference between £24,000 and £45,000 is pretty considerable. Our expenditure has been £28,000. That expenditure would not wholly cover the production of the additional number of lamps, but it would go a very long way towards it. There would be a perceptible addition to the £28,000, but it would be in coal largely. All the other charges would remain the same in amount but less per lamp, and what we have got to strive at is to get that down. Of course, all these things rest on very small calculations. I will give you an idea of what these quantities are—an analysis of what it costs to produce a unit of electricity, 7½d. being the estimated Board of Trade value of a unit. The number of items required to ascertain how much it costs to produce what you can sell for 7½d., or some lesser sum, is 18. As I tried to explain, a portion of that is actually dependent on the quantity you produce, but the bulk is dependent upon a number of fixed charges. In the year 1891 every unit we produced cost us 10·14d., of which 4·61d. was in the first category—generating costs—that is, coal, sundry stores, salaries, wages, repairs and maintenance, and the only thing, therefore, of a fluctuating character which would entail cost for additional quantity is the item of coal, which was 2·36d. per unit. I suppose it is possible that coal may be a little more or a little less per unit. When, however, you come to all the other charges, you have got to divide them by the number

Digitized by Google

of units irrespective of any fact. such as that every unit means so much coal. Every unit does not mean additions to wages, rent, repairs, and maintenance of machinery ; they go revolving and wearing themselves out up to their maximum amount per revolution, and the hope of this thing turns upon what can be done by the multiplication of quantity, and, I admit, trimming down from time to time, as opportunity affords, the charges embraced in those innumerable items which come out in hundredths, and sometimes thousandths, of a decimal of a penny. Just to show how important that is, we have got the three months ending last March, when things had improved from the fact of there being more lights and the machinery having been got into better order, and we have, at some moderate expense, improved the machinery. By means of the condensing process we have diminished the evaporation, and reduced the consumption of coal. In the March quarter of this year, which included only one month of the condensing, we have reduced the cost of the unit from 8·06d. to 5·71d. Of that 5·71d.—the cost of every unit we sold in the March quarter this year—coal stands for 1·31d., and therefore, the enormous proportion of 4·40d. will be stationary, and will be diminished exactly in the proportion as the units sold increase. The only item which will progress will be the 1·31d., or some even smaller quantity per unit, for coal, and the other items embraced in the 4·40d. will diminish and diminish until the amount gets down to probably 3d. or 3½d. per unit. Then you will be able to make your calculation as to the difference between producing a unit at 8d., because you sell a limited quantity, and producing a unit at 3½d. or 4d., where you sell a considerable quantity. I hope I have made this point, which is very technical, clear, but it is very important to those whose pockets have been emptied by experiments in this business. Another important element is the price of selling. All these companies, I believe, are in a very bad position. One naturally looks into their accounts and analyses their figures, and we know as much of the details of these items of all the companies in London as we do of our own. That is our business—by comparison to see where we are. I believe they are all between wind and water ("No, no.") Never mind about "No, no."

A SHAREHOLDER : The St. James's and Pall Mall Company,

A SHAREHOLDER : And the Westminster Company.

The CHAIRMAN : Well, we will not criticise the Westminster Company ; we shall see what they do a year hence. They have all, however, been guilty of an act of folly. I will assume, if you like, that they are as innocent as angels of any want of prudence, but they have been guilty of folly in competition—unduly rushing down the rates. There was no reason why the standard adopted, after enormous inquiry and contention, by the Board of Trade as a legitimate charge, should not have been maintained until, at least, we were out of the wood. When people are prosperous and their position is such that they can pay expenses and make proper reserves, and have large reserve funds, they can begin to give the public the benefit of their excessive profits, but that is not the case with any one of these concerns. Notwithstanding that, we have all got into competition, and the rate has been reduced to 6d. Now, I suppose, human folly can hardly proceed to go further than a standard of something like 6d., under existing conditions, of course. I am not aware that the price of coal is likely to be very materially reduced ; certainly, wages are not, I think, likely to go down. What with Eight Hours' Bills, dockers' unions, and other things directly affecting coal, among others, I should think that the tendency was rather in favour of costs rising instead of falling. In face of that, to knock down a legitimate charge seems open to question ; but there it is. What we have to bear in mind is the standard—what can you sell your article at ? During this year we must take it at 6d., and that makes it very material whether we get down the rate by increase of lights, from 5·71d. to 3½d. or 4d., or some other figure within the bound of 6d. In short, it all comes to this—that the greater the quantity within a reasonable measure the less it will cost, but it is very easy, under the stress of competition, to sell a thing at a price which no cost will justify. That is, so to speak, the philosophy of it. I do not know what anyone is going to say, or what the result of this meeting may be upon the accounts, but what I want the shareholders to carry away in their minds is the only thing which is comforting us and guiding us as to the conditions affecting the sales, and to be accurately informed as to the probability of sales. We think that the probabilities are greatly in favour of our sales increasing, and increasing with reasonable rapidity. When we get double as many lights as we have got now, it will not be so very great a number, and if we get double the number it will make such a marked difference in the cost of production that there will be a considerable profit shown instead of a loss. Now, coming to the report of the Directors, it really only repeats—the bulk of it—the matter which is put there for your edification relating to the views of the engineer. Mr. D'Alton, who was second in command under Mr. Ferranti, we have felt sufficient confidence in to constitute our chief engineer, and he has fully justified that confidence in coping with the enormous difficulties which he has had to incur or to encounter in improving this machine into something like a going concern. Of course, Mr. D'Alton is a mechanic more than a scientist, a pure scientist, and I do not know what the pure scientists would do if it was not for the mechanical brake upon their fancies. But it is necessary in this unknown business to have the assistance of eminent scientists, because there are tests of the utmost delicacy which can only be carried on in a laboratory, and for that purpose we have had the great assistance and advice of Dr. Fleming, who has added to the report his approval and concurrence in what has been said by Mr. D'Alton, while he has given you some crumbs of comfort as to the result of experiments which have shown where in this concern there has been great loss, arising from faults in generating electricity and loss in transmission which have affected the Company very seriously, as you may measure by this fact: that of all the current generated and got into the mains for transmission, only about 42 per cent. is sold in the shape of units, the rest disappearing—fortunately we know now where, and although the knowledge involves the spending of more money, of a moderate amount, it is chiefly in transformers. The new transformers now in course of construction will have this marvellous effect : to reduce the waste. so that we anticipate—or these scientific gentlemen do—that instead of selling 42 per cent. to 45 per cent. of the current, we shall sell 70 per cent. certainly of the quantity produced, or more. That itself will make a vast difference. We tell you in the report about the competition, which has this possible result—that the lower the cost of electric lighting the greater the probability of people resorting to it. I know many people and some companies who have clung to gas because they compare the gas bill with the electric current bill. They think that that is the standard by which they should judge. They say, "Dear me, the electric light costs 20 per cent. or 30 per cent. more than gas, and, therefore, why should I burn the electric light ?" The cost of the electric light, however, does not mean all the benefits of it. One knows what they are. Some of them are sanitary, some æsthetic, some connected with the wall decorations, and so on, in people's houses, but these considerations are very lightly appreciated. People only look at the amount of the bill, and do not take into consideration other advantages. That is knowledge, however, which is spreading, and we believe that it will continue to do so, and it means the development of our business. Of course, the Board regret that the year's working has resulted in a deficit of £3,914. 9s. 7d., but there is some crumb of comfort in this direction, because we have narrowly watched the progress of the thing from month to month and quarter to quarter, and the last quarter of the old year—the year we are dealing with, which ended with December, 1892—and the first quarter of March, 1893, have reversed the position, which is intelligible and satisfactory. In the December quarter of 1891 there was a loss of £821, while in the December quarter in these accounts there was a profit of £1,486. That cuts double. Instead of being a loss of £821 it is a profit of £1,486, so that it is really £2,300 to the good. So, in the March quarter of 1892, there was a loss of £893, while in the first quarter of this year there is a profit of £1,113, representing something like £2,000 to the good. If that goes on, as I trust, we shall only have to wait for a year or two to emerge from a bad state of things into a comparatively satisfactory result. I now move the resolution—

"That the report and accounts now submitted be adopted."

The Right. Hon. the EARL OF CRAWFORD, K.T., seconded the motion.

Mr. BIRKIN asked whether the enormous sum of money—£248,000—paid for the purchase of the business of Sir Coutts Lindsay and Co. had proved a satisfactory purchase, which, he presumed, was recommended by the Directors. He also wished to know whether the present engineer was the gentleman who recommended the adoption of the enormous engines which the Chairman had now said were of no use. It seemed to him (the speaker) that they had to reconstruct and begin *de novo*, and he thought that that was very unsatisfactory. He could not understand why £30,000 had been paid for the cost of redeeming debentures when they had afterwards to get more money. He thought the general expenses were much in excess of what they ought to be, and he considered the Directors ought to meet the existing condition of things by suspending their fees until the shareholders received a dividend.

Other Shareholders having spoken,

The CHAIRMAN, in reply, said it seemed to him to be a choice of alternatives—whether they should take the desponding view of Mr. Barham and and make the worst of it, or accept the extremely common-sense summing up of another shareholder, and the Board preferred the latter course should be adopted. He could not imagine anyone could have a greater interest than the Directors in the undertaking being carried on, and as far as possible successfully, because they held an enormous stake in the Company. Out of the total paid-up ordinary share capital of £555,000 the Directors held £336,000, and, beyond this, they held a very fair share of the preference capital. As he had said, the undertaking was started too magnificently, and the science itself was not sufficiently developed to justify, as it turned out, views which were pleaded with eminent skill and adopted by the Board. That, however, was not a very uncommon state of things in other undertakings. No doubt, the result was unfortunate, but he had endeavoured to make out at the start where they had got to—that they had come through many difficulties, and that the position of disaster had now been sufficiently retrieved to make the future hopeful if they persevered in the course they had undertaken. As to the purchase of the business of Sir Coutts Lindsay, the company was founded upon an existing business, the purchase of which was paid, as he understood, in shares which, with a great many other shares in the Company, belonged to the Directors and their friends who went into the concern with perfect *bona fides*, and who were just as disappointed as their co-shareholders. He had said, elsewhere, and he repeated it, that he never knew any man so like the late Mr. Brunel as Mr. Ferranti, and he remembered that Mr. Brunel broke his heart and diminished his fortune by his gigantic steamship enterprise. The march of ingenuity and the wants of commerce had, however, rendered the adoption of great steamships necessary, and they had come back again. Whether Mr. Ferranti's scheme would be successful in the future or not he (the speaker) could not say, but they could not wait, and therefore must use machines which would accomodate the consumption they had now to deal with. Meantime there was no doubt that Mr. Ferranti's machines did represent a large lock-up of money. The Directors had decided in the future to suspend their fees until the Company was in a position to pay them. He would not allow for a moment that the management had been defective They sometimes had complaints from their customers, and sometimes their lights went out, but that was the case with some other companies too, and theirs was not the only company that was blamed. They endeavoured by canvassers and other means to increase their number of lights, and they could now supply 90,000.

The resolution was carried.

Digitized by Google

The Earl of Crawford was then re-elected a Director as were Sir Coutts Lindsay and Lord Wantage, and the auditors Messrs. Kemp, Ford and Co.

A vote of thanks to the Chairman and Directors was afterwards passed, and the proceedings terminated.

The following is an abstract of the Directors' annual report for 1892 :—

The measures taken to reduce the cost of producing the current and increase the efficiency of the generating plant have proved satisfactory. Owing to the autumn being the only period of the year when extensive alterations or additions to the generating machinery can be prudently carried out, the advantages gained were but slightly felt during the past year, but, as stated in the engineer's report, the current year will realise the full benefit of the work done. As a consequence of the competition which has arisen among the several companies, the standard charge per unit has been reduced from 7½d. to 6d. The electric current at its present cost being now about equal to that of gas, the Board feel justified in anticipating a rapid extension of electric lighting.

The increase in the number of lights supplied during the past year amounted to about 40 per cent. This rate of increase has been more than maintained during the first four months of the current year, and in face of severe competition. The Board regret that the year's working has resulted in a deficit of £3,914. 9s. 7d., which is partly due to the slow rate of increase of the business in the early part of the year, and partly to the diminution in the number of units sold per lamp installed. It may, however, be observed that a comparison of the accounts shows that, whereas in the December quarter of 1891 there was a loss of £821. 5s., there has been a profit of £1,486. 15s. 10d. in the corresponding quarter of 1892, and that in the quarter ended March, 1892, there was a loss of £833. 13s. 1d., there has been a gain of £1,113. 8s. 8d. in the corresponding quarter of the current year. Major C. B. Waller, formerly manager and secretary, has been elected a Director in the place of Mr. Arthur F. Wade, resigned. Mr. Henry F. Lewis, for many years general manager of the Western Counties and South Wales Telephone Company, has been appointed general manager ; and Mr. R. Stewart Bain, the accountant, has—while retaining that post—been appointed secretary.

Particulars of the working of the Company's system will be found in the reports below.

Report by Mr. P. W. D'Alton, engineer-in-chief, dated May 4, 1893 :—

"During the past year the working has been satisfactory, and many improvements in mechanical and electrical details have been made with the best result ; so that, of late, the interruptions in the supply of current have been few and unimportant. At the commencement of the year we had 35,100 lights connected. At the end of the year the number had increased to 46,197. Up to the present date the number amounts to 56,200 lights, and we have orders for a considerable number of lamps in course of execution.

Important additions have been made to the generating and other plant. A new dynamo of 300 H.P., driven by a set of triple-expansion condensing engines, has been erected, from which we have obtained excellent economical results. This machine is able to deal with the early-morning load during a considerable part of the year. A machine of similar size is now being built for us, which, when brought into use, will enable us to work our daylight load with greater economy than has hitherto been possible. These machines will constitute a useful auxiliary power, as they can be worked in parallel with the larger machines with considerable economy. The remodelling of the two 625 H.P. dynamos has been effected, and the output of the machines increased from 8,500 lights to 12,500 lights each, an advantage which has been secured by a relatively small outlay. The high-tension transformers, which gave us so much trouble in previous years, have done their work well. This I attribute to the careful and intelligent manner in which these instruments have been overhauled in our repairing departments at Deptford.

The trunk mains have worked satisfactorily during the year. They were very seriously threatened, and suffered considerable damage, by two fires which occurred on premises contiguous to the mains. To safeguard us in future from such consequences, I am now laying underground mains in substitution for those affixed to the S.-E. Railway parapet. When this work is completed the whole of our trunk mains will be underground, with the exception of the short section which crosses the river by Charing Cross Railway Bridge.

During the year we have laid down eight miles of distributing mains, making a total of about 35 miles of this description of main, all of which are in a satisfactory condition. The whole of the distributing stations now in use are fully equipped with the permanent switching gear, and these stations are working well. The system for condensing the exhaust steam has been completed during the year, and has been in work for some months past with the economical and mechanical advantages which I anticipated. The generating and distributing plant has been kept during the year in good order, and is working to my entire satisfaction.

Dr. J. A. Fleming, consulting engineer to the Company, reports under same date :—

I have read the report of your engineer, and substantially agree with the same. In addition to the remarks made by him, I may add that at the beginning of the year 1892 I began to carry out a careful series of experiments on the energy losses in the house-transformers. The result of this investigation was to show that an immense improvement could be effected in the Corporation's system by replacing the existing house-transformers by others of a more modern type. This work you have now sanctioned, and it is being carried out, and the result will be to effect a great economy in fuel. In the course of these experiments we discovered a very simple method of regulating electric pressure, which we have applied to the trunk mains with satisfactory results, in that we are now able to connect and disconnect mains without producing changes of electric pressure injurious to them.

The high-tension transformers have, during the last year, given very little trouble. The methods of connecting and disconnecting them to the circuits have been so far perfected that failures of these transformers are now very rare. When the replacement of the whole of the house-transformers is effected, and when the other improvements described by your engineer are all fully at work, I think there is every reason to believe that the system of supply will, so far as economy and efficiency of working is concerned, compare very favourably with other systems.

Yorkshire House-to-House Electricity Company (Limited).

The annual meeting of the shareholders of this Company took place at the offices, Whitehall-road, Leeds, on Friday, Mr. Grosvenor Talbot in the chair.

In moving the adoption of the report, which was published in *The Electrician* of May 5th, the CHAIRMAN said it only showed a very small part of the work that had been done. Since December 31st they had considerably advanced ; they had opened their works, and they should have very much more to tell the shareholders a year hence. The Directors considered that they had done well, and the presence of so many people from various parts of the country at the opening of their works on Wednesday showed that there was evidently great anxiety on the part of large towns throughout the United Kingdom as to obtaining the best system of electric lighting. They trusted that their works were on the best existing plan, and there was every reason to believe that they would be efficiently conducted by the Directors, for their coal and water were cheap and their situation good. They felt sure that the works would be keenly criticised, but he hoped they should do everything in their power to make them a success. He thought the shareholders would join in the opinion of the Directors that so far they had proceeded in the right direction, and it now remained for them to go further and make the works which they had commenced a successful paying concern. They could with their plant provide current for 5,000 or 6,000 lamps more than they were now supplying, and when these were taken up they trusted they should be able to get additional capital for the extension of their plants. In conclusion, the Chairman explained that the expenses in connection with the opening of the works did not fall upon the shareholders in the slightest degree.

Mr. ROBERT HUDSON seconded the motion, and the report was unanimously adopted.

Messrs. Robert Hudson and Samuel Ingham were afterwards re-appointed on the Directorate, and Mr. John Gordon, jun., was re-elected auditor.

In reply to an inquiry from a shareholder, the CHAIRMAN stated that with their present plant they could supply 16,000 8-candle lamps, and that between 10,000 and 11,000 lights had been applied for up to the present.

The meeting then concluded with a vote of thanks to the Chairman.

China and Japan Telephone Company (Limited).

The tenth ordinary general meeting of this Company was held at the offices, 14, Austin Friars, E.C., on Tuesday, Mr. Thomas Lloyd presiding. We have been supplied with the following report of the proceedings :—

The SECRETARY (Mr. Alex. B. Chalmers) read the notice convening the meeting.

The CHAIRMAN : Gentlemen, the report and accounts have been in your hands for some days, so I presume you will take them as read. I do not know that I need detain you with very many remarks. The Company is doing satisfactorily, and we carry forward a favourable balance. The business looks improving in spite of difficulties in regard to the depreciation of silver. Mr. Porter, our manager in Shanghai, has been, as some of you know, at home for a year, and has reported very favourably as to the future. Mr. Harrison, the Company's representative at Hong Kong, has put that agency on a better footing, and the latest accounts from him are decidedly encouraging. I now beg to move—"That the Directors' report and the audited accounts for the period ending 31st December, 1892, be, and they are hereby approved and adopted."

Mr. GREWING seconded the resolution, which was carried.

Mr. GREWING then proposed—"That Mr. Thomas Lloyd be re-elected a Director of the Company," which was seconded by Mr. W. ADDISON, and carried.

The retiring auditors having been re-elected, it was proposed by Mr. W. ADDISON that a sum of two hundred guineas be voted to the Directors for their services during the past year. The motion having been seconded and carried, the proceedings terminated.

The following is the Directors' report :—

The revenue account for the year ending December 31, 1892, after charging interest on debentures, shows a balance to credit of £549. 15s. 7d., which has been transferred to profit and loss account. Including £627. 9s. 11d. brought forward from 1891, the amount to credit of this account is £1,177. 5s. 6d. The expenditure on capital account being £482. 2s. 2d. in excess of the share capital and debentures issued, it is proposed to charge profit and loss with that sum by writing off the amount to credit of capital account, and to carry forward the balance, viz., £695. 3s. 4d. There has been an increased business during the year at both Shanghai and Hong Kong, but the fall in exchange consequent on the depreciation of silver has affected the final result of the year's accounts, the amount charged in the accounts in respect of this item being £243. 19s. 4d.

Elmore's Patent Copper Depositing Company (Limited).

The adjourned extraordinary general meeting of this Company was held on Friday last, at the Cannon-street Hotel, E.C., Mr. J. Todhunter, J.P. (one of the provisional Directors), in the chair.

The CHAIRMAN said that the subscriptions to the required sum of £17,600 amounted to only about £12,000, and the Committee had pledged themselves that, if the whole amount were not forthcoming by Tuesday last, the cheques received should be returned. On his own responsibility he had approached some financiers with a view to obtaining funds, and two days ago he had an absolute promise of a guarantee of the whole capital that would be required for the reconstruction of the Company; since then there had been a panic in financial circles, and the offer was withdrawn. He proposed that the Company should go into voluntary liquidation, and sell the assets to a new company, with a nominal capital of £200,000, with 182,390 shares of £1 each, carrying a liability of 3s. on each share, each shareholder in the existing Company to receive two shares of £1 each for every £2 share now held by him. That would provide a working capital of about £10,000, which was absolutely necessary to complete the machinery and put the works on a proper basis. From personal knowledge and inspection he was confirmed in the opinion that the process was a success. He therefore proposed the adoption of the scheme.

Mr. INVERARITY suggested the issue of a circular, inviting the shareholders to subscribe *pro rata* towards the £5,000 now required.

Mr. F. L. RAWSON proposed as an alternative scheme the creation of second mortgage debentures, with the option of holders exchanging at any time into ordinary shares.

Ultimately, a canvass of the shareholders in the room was taken, when subscriptions for preference shares were announced to the extent of £2,730, in addition to the £12,000 promised. It was also decided that the secretary should issue a circular appealing for funds.

A resolution was then moved and adopted:—"That, in the event of the money not being forthcoming by Tuesday, the Directors be requested to convene a special meeting to wind up the Company with a view to reconstruction."

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1893, pages 320-348, *&c., &c.*]

BOURNE AND GRANT ELECTRICITY SUPPLY COMPANY (LIMITED).—This Company was registered on the 13th inst. with a capital of £25,000, divided into 24,900 ordinary shares and 100 founders' shares of £1 each, to carry on the business of an electric light, heat, and power supply company in all or any of its branches, and to carry on the business of electricians, electric light contractors, electrical and mechanical engineers, suppliers of electricity for the purpose of light, heat, motive power, or otherwise, and manufacturers of and dealers in electrical apparatus of every description.

COVENTRY ELECTRIC TRAMWAYS (LIMITED).—This Company was registered on the 10th inst., with a capital of £25,000 in £5 shares, to acquire railways, tramways, &c., in the United Kingdom; to construct, maintain, work, equip, lease, or obtain running powers over, or to dispose of, such railways or tramways; to adopt and carry into effect an agreement dated May 5, 1893, and made between the Electric and General Contract Corporation (Limited) and Alfred G. Jones (as trustee for the present Company); and to carry on the business of contractors for electric traction, carriers, electrical and general engineers, electricians, suppliers of electricity, and manufacturers of and dealers in electrical and scientific apparatus.

MISCELLANEOUS.—THOMPSON BROTHERS (LIMITED), mechanical and electrical engineers, gas-oven makers, and iron and brass founders; capital, £7,000 in £1 shares.——WEST HAMPSTEAD FOUNDRY AND ENGINEERING COMPANY (LIMITED), mechanical and electrical engineers, iron and brass founders, machinists, &c.; capital, £15,000 in £1 shares.

J. E. H. ANDREW AND CO. (LIMITED).—The annual return of this Company made up to April 13th has been filed. The nominal capital is now £40,000 in £20 shares, 1,465 shares have been taken up, of which 300 have been issued as fully paid. Upon the remaining shares a call of £20 per share has been made, resulting in the payment of £24,000, which includes a sum of £700 paid on 35 forfeited shares.

ANGLO-PORTUGUESE TELEPHONE COMPANY (LIMITED).—The annual return of this Company, made up to April 11th, has been filed, and shows that out of a nominal capital of £75,000, in £1 shares, 50,000 shares have been taken up, all of which have been issued as fully paid. Of these share warrants comprising ten shares each are outstanding to the total amount of £4,020.

BERNSTEIN ELECTRIC LAMP COMPANY (LIMITED).—The Registrar of Joint-Stock Companies has been informed by Mr. D. Havelock Fisher, the secretary, that although no business has been done by the Company during 1892, the patents are being kept valid, and the Company will be kept on in the hope of business being renewed.

BIRMINGHAM ELECTRIC SUPPLY COMPANY (LIMITED).—The annual return of this Company, made up to March 20th, has been filed. The nominal capital is £100,000, in £5 shares, all of which have been taken up. The full amount has been called on 10,000 shares, and £2 per share on the remainder, resulting in a total payment of £70,000.

CHAMBERLAIN AND HOOKHAM (LIMITED).—The annual return of this Company made up to April 26th has been filed. The nominal capital is £100,000, divided into 5,000 "A" and 5,000 "B" shares of £10 each; 1,000 "A" and all the "B" shares have been taken up, the latter having been issued as fully paid to the vendors. Upon the "A" shares a call of £3. 10s. per share has been made, and all calls have been paid.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—The second annual return of the above-named Company, made up to April 27th, has been filed; 20,000 preference and 40,000 ordinary shares have been taken up, out of a nominal capital of £800,000, divided into 40,000 preference shares of £10 each, and a like number of ordinary shares of £10 each. The full amount has been called on the ordinary shares, while a call of £8 per share has been made on the preference shares. The calls paid amount to £560,000.

DOMINION ELECTRICAL COMPANY (LIMITED).—The statutory return of this Company, made up to March 10th, has been filed, and shows that out of a nominal capital of £25,125, divided into 5,000 ordinary shares of £5 each and 500 founders' shares of 5s. each, 1,000 ordinary and all the founders' shares have been taken up. Upon the founders' shares the full amount has been called, while each of the ordinary shares has had £1. 5s. called upon it. The calls paid amount to £1,750.

NOTTINGHAM ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—A meeting of this Company (in voluntary liquidation) is to be held at 29, Low-pavement, Nottingham, on June 12th, at 4 p.m., to receive the liquidator's report of the winding-up.

WILLIAMSON ELECTRICAL ENGINEERING COMPANY (LIMITED).—At a meeting of the Company, held on the 2nd inst., at 14, St. Ann's-square, Manchester, it was resolved to wind up the Company voluntarily. Mr. J. E. Sharples, of the above address, was appointed liquidator, and claims must reach him by October 2nd.

WOODHOUSE AND RAWSON ELECTRIC MANUFACTURING COMPANY (LIMITED).—A meeting of this Company is to be held at Room 433, 11, Queen Victoria street, E.C., on June 16th, at 3 p.m., to receive the liquidator's account of the winding up.

WOODHOUSE AND RAWSON UNITED (LIMITED).—A petition for the winding up of this Company has been presented by W. T. Henley's Telegraph Works Company (Limited), and is directed to be heard at the Royal Courts of Justice, on the 7th prox.

CITY NOTES, &c.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended May 14th were £787, as against £769 for the corresponding period of last year, being an increase of £78. The total receipts for the half-year amount to £16,940, against £15,607 in the corresponding period of 1892, being an increase of £1,333.

GENERAL ELECTRIC COMPANY (U.S.A.).—The first annual report of this Company, which was incorporated in April, 1892, has just been issued. It will be remembered that the Company acquired the capital stock of the Edison General Electric Company, the Thomson-Houston Electric Company, and the Thomson-Houston International Electric Company. The report shows that the Company has about 6,000 customers, and that the chief increase in the business since the incorporation has been in the lighting and railway departments 1,277 local lighting companies, who are customers of the General Electric Company, are stated to be supplying about two and a-half million incandescence and about 110,000 arc lights, and the increase in mileage of the railway companies using the Edison and Thomson-Houston systems has increased from 2,315 miles in 1892 to 4,927 miles in 1893: whereas in 1892 the largest power generators manufactured was of 275-H.P. machines of 2,000-H.P. are now being manufactured. The largest lighting generators at the same date were for 2,000 incandescence, and are now being constructed for 12,000 lights. Considerable progress has been made in the development of electrical apparatus for mining purposes and in particular of locomotives for haulage work, for which the Company have a large number of orders for early delivery. The report states that in addition to the actions which it has been found necessary for the Company to take during the past year to protect these patent rights, other actions are in progress, and are to be pushed on as vigorously as possible. The Company are represented to be supplying plant and apparatus to about 1,300 local companies who are paying royalties from 1,500,000 dollars to 2 millions dollars per annum. The Company is making much progress and is paying regular quarterly dividends.

REUTER'S TELEGRAM COMPANY (LIMITED).—Notice is given that the twenty-ninth ordinary general meeting of the shareholders of this Company will be held on Wednesday, the 31st inst., at 12 o'clock at the offices, 24, Old Jewry, E.C., for the reception of a report and balance-sheet from the Directors, the declaration of a dividend, and the election of a Director and auditors; and to pass a resolution with reference to the Superannuation Fund.

THE LATE SIR JAMES ANDERSON.—At the Board meetings of the telegraph and other companies with which the late Sir James Anderson was associated, feeling references have been made during the past week, and votes of condolence with his family, expressing a high sense of the eminent services rendered by him to submarine telegraphy, have been unanimously passed.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 784.—Vol. XXXI. FRIDAY, MAY 26, 1893. PRICE FOURPENCE.
Annual Subscription (U.K.), 19/6

NOTES.

As will be seen by a Note in another column, the Municipal Corporations Association and the London County Council have been moved to take part in the Telephones *v.* Electric Traction Battle. The case for electric traction is, we have always contended, a strong one. Unfortunately, it has, until lately, lacked lucid exposition just where it was most needed, namely, at Westminster, and it has been without influential backers. With the signatories of last week's manifesto, the Municipal Corporations Association, and the London County Council all bestirring themselves, these two factors of success will no longer be absent.

The ingenious magnetic curve tracer of Prof. Ewing appeared at the conversazione of the Royal Society a fortnight ago in its final practical shape. The earlier form of this instrument, and the curves produced by it, have already been described in our columns. Engineers have been long familiar with the measurement of the area of indicator diagrams for arriving at the power developed by steam-engines, and it is safe to say that, out of every three who can thus make a satisfactory calculation of I.H.P., only one can give an intelligent account of the information about valve-setting and other details which are revealed by examination of the diagram. Similarly, we hope that this instrument may be practically used by those who do not aspire to master the intricacies of the phenomena of the magnetisation of iron. Having sample bars as a guide, manufacturers should be able to acquire valuable relative information about their iron, even if they do not trouble themselves about ergs per cubic centimetre. We should like to see this instrument in the laboratories of iron manufacturers, for it is to them that dynamo-makers may reasonably look for guarantees, or, at all events, offers of suitable material. We may observe that the curves, Figs. 5 and 6, in the article in our present issue, are one-fifth the size of the curves drawn by the apparatus itself. The dots show the actual readings, and the smoothness with which the curves run through them are a singular proof of the accuracy of the instrument.

At one time there was an idea that nothing could touch Swedish charcoal iron. Then Lowmoor iron, unrivalled for softness for certain mechanical work, was supposed to be equally unapproachable for field magnets. Then Kirkstall Forge undertook to anneal forgings for some thirty days or so for patient dynamo-builders. This groping about for good magnet iron was hard enough; but the great difficulty was to attain uniformity. A small maker might by accident turn out good material, but, not knowing why, could not reproduce it. Safety thus lay in obtaining material only from large producers. For armature cores, for which Prof. Ewing's instrument presents special advantages, the dynamo-maker has happily been assisted by the fact that iron which is magnetically bad cannot be rolled out into thin plates. But, as in the case of iron wire to which the same observation applies, repeated annealing tends to burn "the nature" out of it, to use a time-honoured ambiguity. We have more than once expressed a hope that iron manufacturers, many of whom are already equipped with excellent laboratories, might be induced to study the requirements of dynamo-makers. A knowledge of the magnetic properties of their brands would be useful, but the real question, and one which the electrician cannot be expected to attempt, is the relation between these properties and the chemical constitution of the iron.

The automatic insulation indicators used in Berlin seem to be well worth the attention of English engineers. It is strange that while such enormous sums have been spent, not only in copper, which may be expected to last for an indefinite time, but in insulating materials the life of which but little is known, and while much has been sunk in the labour of laying electric-supply mains, the safety of this valuable property is left very much to chance; and when a fault occurs, the guess of the foreman is generally taken as the best indication of the whereabouts of the accident. In America a regular staff of "trouble-men" are employed, and by long experience quickly discover the nature and exact locality of a short circuit or "ground." The Berlin system, which is described in another column, provides a continuous watching of the insulation by means of a system of pilot wires and relay indicators. Pilot wires for voltmeters are common enough in this country, but some engineers find that they have more trouble with the faults in the insulation of their pilot wires than with the whole of the rest of their lines. When once such a system as the one used at Berlin is introduced, it must be carried out thoroughly, for the earthing of the network at numerous points through pilot wires and relays would interfere with other modes of testing the insulation.

Mr. Thomas Fletcher in the opening lines of his letter, which will be found in our Correspondence columns, uses

Digitized by Google

hard words about Mr. DOWSING's communication of last week; but whatever was lacking in that will be found in Mr. BINSWANGER's letter in our present issue. Mr. BINSWANGER's calculations agree excellently with those to which we referred last week, and are practically identical with those of our correspondent, Mr. LESLIE MILLER. Mr. BINSWANGER takes a pint of water at 15°C. and 1,000 watts, and arrives at 3·383 minutes for the theoretical time required to boil it. We took a pint at 20°C., and allowing five minutes, found that 625 watts would be required. We went on to admit that half a cubic foot of gas costing (at 3s. per 1,000) 0·0182d. would do the same, and are glad to take this opportunity of stating that, in arriving at this estimate, we consulted the figures published by Mr. FLETCHER. We attempted, at the same time, to ascertain from the same source the specific heat of a mutton chop; but could only guess that it was probably not much above 0·5. Our estimate of the gas consumption appears to be very much below the mark, if applied to the boiling of a single pint of water. The efficiency of 10 or 11 per cent., which Mr. BINSWANGER claims to have attained with a kettle, is remarkable; but it should be observed that, as we pointed out last week, the cost of warming-up is a great burden on electrical heating. In his test of an oven, it appears that, while the whole operation took two-thirds of a supply unit, the warming-up took nearly one-half of this, or one-third of a unit. The units spoken of by Mr. FLETCHER, by-the-bye, are, of course, thermal units.

In view of the recent crop of high-frequency alternators, it may be interesting to note that as long ago as 1849 PULVERMACHER invented an alternator which had a frequency of several thousand periods per second. This machine had an armature with 40 poles, so that if coupled to a Parsons steam turbine running at 8,000 revolutions per minute, it would have a frequency of 2,667 $\sim$ per second. Both field-magnets and armature were constructed of laminated iron plates, and in order to work with a microscopic air-gap, arrangements were provided for setting the armature concentrically with the magnets. To satisfy the prevailing demand for big figures, we may observe that if PULVERMACHER's alternator had been started running forty-three years ago, it would by this time have completed upwards of 7,230,000,000,000 alternations. In this calculation no account has been taken of the extra day in the leap-years.

THE Chicago Exhibition has, we must frankly confess, been somewhat of a strain upon our small stock of philosophy. A new era gets itself "inaugurated" with about ·01 per cent. of the fuss that has been made over this raree show. But now that the dollared public have been permitted to gaze upon an archipelago of packing-cases encircled by a sea of mud, the English language threatens to give way under the tremendous demands made upon it by its transatlantic users in their vain endeavours to write up to the height of the occasion. An American contemporary, devoted to tramways, remarks that as a rule the actual falls lamentably short of the ideal, but not so in the case of the Chicago Exhibition, where "no such regret will be expressed, for the simple reason that it does not lie within the power of writer and artist to convey anything like an adequate conception of the beauty, extent, and grandeur of the World's Fair. From its inception the work has been prosecuted with that tremendous energy which has built up a city of a million and a-half in half a century, and whose citizens, from the multi-millionaire down to the day labourer, have gladly contributed according to their means and expended fifteen millions of money in providing an aggregation whose equal the sun has never shone upon before. It is but truth, and in no measure exceeding the bounds of modesty, to say that what Chicago has done in this great enterprise would not, and, indeed, could not, have been accomplished by any other city on the continent, nor by any city on the globe within the same time."

THE "car fender," a transaltantic contemporary gravely informs us, "is a subject which may well enlist the consideration of the thoughtful manager." Not being acquainted with American tramway practice, we will take that statement as correct. When, however, we are asked to believe that "as a matter of economy in self-protection alone the fender would seem to admit of little argument in most cities and towns," we have no hesitation in professing our preference for the contents of a fender—which may be expressed by the well-known formula, Pkr + Tngs + Shvl—as being operators of far greater value as a means of self-protection than the fender itself.

Cardiff.—The Local Government Board has sanctioned the electric lighting loan of £32,500.

The Electric Lighting of the British Museum.—The substitution of incandescent lamps for arc lamps is in process of being carried out at the British Museum.

The American Philosophical Society.—The American Philosophical Society is celebrating its 150th anniversary at Philadelphia this week by a series of scientific and social assemblies.

The Board of Trade.—The President of the Board of Trade has appointed Mr. Francis J. S. Hopwood to be Assistant Secretary of the Railway Department, in the room of Sir Courtenay Boyle, K.C.B., promoted.

The Proposed Electric Railway in Berlin.—The proposed Berlin elevated electric railway has, says the *Engineer*, been blocked for another year, on the ground that it would interfere with services in a church.

Electric Traction at Bordeaux.—The Thomson-Houston International Electric Company has signed a contract with a Bordeaux Tramway Company to equip its system with electrical apparatus by September 30th next.

The Forthcoming International Electrical Congress at Chicago.—The five English delegates at this Congress will be Mr. W. H. Preece, Prof. W. E. Ayrton, Major Cardew, Mr. Alexander Siemens and Prof. Silvanus Thompson.

The Discussion on Mr. W. B. Sayers' Paper.—We have held over our report of the discussion on Mr. W. B. Sayers' Institution Paper, printed in our last issue, until next week, in order that our readers may have it complete and revised.

A Large Electric Traction Order.—The Westinghouse Company recently received a contract from the Philadelphia Traction Company for 600 electric railroad motors and 8,500 H.P.

Digitized by Google

generators. It also has the contract to supply all the electrical apparatus.

The Statue of Claude-Chappe.—The Statue of Claude Chappe, the inventor of the semaphore telegraph, is to be inaugurated on July 13th next. The Paris Municipality has granted a site. The subscription started by the French Telegraph Administration reached a total of £1,400.

Cable Interruptions and Repairs:—

	Interrupted.	Repaired.
Para-Maranham	March 20th. ...	May 21st.
Assab-Massowah	March 15th. ...	May 25th.
Paramaribo-Cayenne	April 15th. ...	—
Santiago de Cuba-Mole St. Nicholas.	April 20th. ...	—

Appointments.—Sir John Pender has accepted the Chairmanship of the Brazilian Submarine and Direct Spanish Telegraph Companies. Mr. J. Denison Pender has been appointed Managing Director of the Eastern, Eastern and South African, and West African Telegraph Companies, in place of the late Sir James Anderson.

A New Wimshurst Machine.—Mr. Wimshurst has brought out a new type of influence machine. It consists of two similarly-rotated plate-glass discs placed about $\frac{3}{4}$in. apart. In the intervening space there are four vertical sheets of glass upon each of which there is a paper inductor. Brushes bear upon the inductors and upon the outer edges of the discs. There are also neutralising brushes.

The Telephones and Electric Traction.—At a meeting of the Council of the Municipal Corporations Association last week, the action of the National Telephone Company in regard to tramways worked by electricity was discussed, and a resolution proposed by the Town Clerk of Manchester, and seconded and supported by the Mayor and Town Clerk of Leeds, was passed, declaring that the matter was of such importance that it should be dealt with on Thursday, June 1st.

Electric Traction at Bangkok.—The *Indian Engineer* gives the following particulars with regard to the "Short" electric tramway at Bangkok. The plant consists of two 80-H.P. McIntosh-Seymour engines running at 284 revolutions, and two 100-ampere 500-volt generators. The overhead wire consists of No. 2 hard-drawn copper, and is suspended by steel brackets and insulated hangers from poles at the side of the road. The entire length of 17,200ft. is in three pieces only, joined by two sleeve joints. The cars are provided with 20-H.P. motors.

Munich.—The streets in the central part of Munich are to be lighted by electricity. It is proposed to utilise the water-power of two places near the town, and the whole work will be carried out before October next by Messrs. Schuckert and Co. of Nuremburg. Three hundred arc lamps are provided for, and by means of accumulators the town hall will be lighted with 1,800 incandescent lamps of 16 c.p. each. It is anticipated that before long double the original number of arc lamps will be wanted. The arc lighting is to be carried out on the three-wire system, each dynamo giving 250 volts, so that 550-volt arc lamps can be grouped in series across each branch.

Defining the Candle-power of Arc Lamps.—In a letter addressed to Prof. Elisha Gray, Chairman of the Electrical Congress Committee, the representatives of various electric-lighting interests in Chicago call attention to the confusion which is caused by designating arc lamps as of 2,000 c.p., 1,200 c.p., &c. The following is proposed for discussion and adoption by the forthcoming Congress:—"The term 2,000 c.p. is to mean an arc produced by 10 amperes and 45 volts potential-difference between the carbons, or a 450-watt arc. The candle-power of arcs produced by currents of more or less amperes, or more or fewer volts difference of potential to be rated proportionally."

The Town of Ampere.—A promising commencement of a town, with one of the fathers of electricity as its tutelary genius, has, say the *Electrical World*, been made in New Jersey, and the indications are that it will prove worthy of the great name it bears. At present the great establishment of the Crocker-Wheeler Electric Company, the electric enamelling works of George Cutter, and a pretty railway station are the only buildings. The Crocker-Wheeler Company have purchased six acres of land, and extensive buildings in which they will carry on their manufacturing are being fitted up. Shafting is entirely dispensed with, electric circuits of copper rods, tapped at intervals to supply the motors, taking their place.

The Electrical Utilisation of Water Power.—A company has been formed in Zurich with a capital of £40,000. It is proposed to establish a central station in which the water power of the Sichl, near Wedensweil, will be utilised. It is estimated that 1,300 H.P. will be available.—Plans have been prepared for the electric transmission of power from Snoqualmie Falls to the City of Seattle, Wash. The falls, it is estimated, will furnish some 32,000 H.P. at all seasons of the year; the distance to Seattle is 24 miles across a lake in a direct line, and nearly 40 miles by land. Seattle has now about 40,000 inhabitants, and is a manufacturing town with many miles of tramways. On the other hand coal of fair quality is very cheap, being about 5s. per ton in large lots.

Electricity Applied to Farm Work.—An interesting example of electricity as applied to farm work has been in operation for some time at Ardwell, Wigtownshire. The whole of the usual farm machinery—such as threshing, sawing, corn-crushing, and the like—is here driven by an electric motor. Power is generated by water, the turbo-dynamo being about a thousand yards from the farm. The current is conveyed underground to the house and farm, in each of which a storage battery is placed. The whole of the house is lit with the electric light, and an electric motor is provided for pumping water for domestic purposes. At the farm, which is also lit throughout with the electric light, there is a 16-H.P. motor, which is arranged to drive the farm machinery.

Telephone Wires.—On Monday last the representatives of the National Telephone Company and the Broughty Ferry Police Commission met in Dundee to consider the question of rent for wayleave for the Company's posts, a question raised by the Commissioners requesting payment of a fixed sum per annum per post, and also for each wire on the posts. The representatives of the Company offered (1) a rent of 1s. per pole, which means a sum of £2. 14s., there being 54 poles on the streets; (2) the continued free use of the instrument at the Police Chambers; (3) an instrument for the use of the Parochial Board at half-price; (4) two new call offices for the convenience of the public; and (5) a reduction of the three-penny tariff rate for conversation to Dundee to one penny. The Commissioners' representatives considered the terms offered quite inadequate for the privileges the Company enjoys, and told its representatives they had no hope of their Board agreeing to the Company's proposals, also giving them to understand that, unless more liberal terms were offered, the Company would have to remove their posts off the streets immediately after June 14th next.

The City and Guilds of London Institute and Technological Examinations.—A letter has been addressed to County Councils throughout the kingdom, and to the secretaries of technical schools in connection with the City and Guilds of London Institute with respect to the altered conditions consequent on the passing of the Local Taxation Act, under which the Institute's examinations will in future be conducted, and indicating the kind of assistance which the Institute will be prepared to give in the way of directing technical instruction, of examining the students of technical classes, and of awarding certificates and prizes. The Committee of the Institute have adopted a scheme, and are prepared to receive applications from County Councils or school committees for the inspection of classes in technical subjects, and also for special reports on the results of the examination of the students of separate classes registered under the Institute. The Committee propose to appoint two inspectors, one in connection with the engineering and allied trades, and another with the manufacture of textile fabrics; and they further propose to appoint a third inspector for industries involving applications of chemistry, and possibly others, as occasion may require.

Trade Classes at Finsbury.—The following paragraph, relating to the Finsbury Technical College trade classes, taken from

Digitized by Google

the annual report of the Principal to the Governors of the Institute is instructive :—

The Trade Classes show a decrease of 33 students, the entries being 150, as compared with 183 last Session. The instructors of these classes have worked willingly and well, and have the success of their students thoroughly at heart. The falling off is not attributable to any want of earnestness on their part, but is due to several causes, chief of which are the insufficient public information given of the existence of these classes, and the competition of classes of a somewhat similar description in other institutions that advertise, not only in their own districts, but all over London. In view of the present movement for establishing technical institutes in various localities in London under the scheme of the Charity Commissioners, it is worth while to consider whether, under the circumstances attendant on our Trade Classes and the limited accommodation we are able to afford them, it would not be a decided advantage to these classes and to the persons attending them if they were handed over to some one of the proposed Technical Institutes, where better provision could be made for them than is possible under present circumstances, and where they might benefit from being associated with a Building Trades School held in the daytime. To sever from Finsbury these classes, which have existed since 1873, would be, no doubt, a loss to the College, but that our loss would be their gain cannot be doubted by anyone acquainted with the limitations which, under existing conditions, circumscribe their usefulness.

Thunderstorms.—On Saturday last the Newcastle-on-Tyne district was visited by severe thunderstorms, and a Mr. Robert Taylor was killed in the course of the afternoon by lightning at Harton. He was at the time engaged in holding a galvanised iron pipe, attached to a hose pipe, and was watering some clay. Portions of the deceased's clothing was found fifteen yards off. About half the clothing was torn away from the body, and the left boot was taken off. During the morning the nail manufactory of Mr. Galloway, at Gateshead, was struck by lightning and a chimney was partly demolished, three persons being injured. In the afternoon houses at Gateshead, Walker, and Gosforth were struck by lightning and damaged. At Medomsley, on the previous day, whilst a deputy over-man, named John Walton, was proceeding to his work at the Consett Iron Company's Derwent pit, he was struck by lightning as he was passing through the fields about 200 yards from the colliery. One of his shoes was taken off his foot and the other shoe was cut in several places. Part of his clothing was lying fully twenty-three yards from where he fell. Houses and cattle are reported as having been struck in the North, South, East, West, and Midlands. At Hartlip, in Kent, two labourers, who sought shelter from a storm under an elm tree, were injured by a discharge which stripped the bark off the tree.

Engineering at Cambridge.—The Syndicate appointed to make arrangements for the further development of the Cambridge Engineering School have reported to the Senate, and submitted plans for an engineering laboratory, prepared by Mr. W. C. Marshall, of the firm of Marshall and Vickers, architects. The Syndicate state that they were fortunate in securing the co-operation of a number of engineers and others interested in the development of an engineering laboratory in the University. A Committee was formed to invite subscriptions. The subscription list was opened by a gift of £1,000 from the Chancellor, and the total amount subscribed up to the present time is £4,847. 16s. Several important contributions of apparatus have also been made towards the equipment of the laboratory. A part of the sum collected has been spent in providing apparatus for immediate use, and about £4,100 remains available for building, or for the purpose of additional apparatus. With the establishment of a tripos in mechanical science (November 10, 1892) the work of the department has increased to such an extent that the existing accommodation is inadequate. There are now sixty-two pupils in attendance, most of whom are engaged on a systematic course of study in mechanical science. The Syndicate do not propose to carry out the plans at once in their entirety, but ask to be authorised to proceed with such portions of the work as they are able to execute with the funds at their disposal.

The Electrical Equipment of the McGill University.—We are indebted to Prof. Carus-Wilson for the following interesting particulars with regard to the electrical equipment of the Applied Science Buildings at the McGill University, Montreal. The buildings are lighted throughout by the electric light, the lighting station being an essential part of the Electric Engineering Laboratories. The plant consists of two 30-kilowatt dynamos, a Siemens and an Edison-Hopkinson, giving 105 volts at 460 revolutions. They are driven direct by two 60-H.P. Willans engines. The main switchboard is arranged so that the lighting may be carried out either on the three-wire or the two-wire system or by accumulators. The main circuits supply current to the Engineering and Physics Buildings, in which there are respectively 1,200 and 500 16-c.p. lamps. There are also six arc lamps, a 10-H.P. motor for working a lift, two 5-H.P. fan motors, and seven smaller motors driving lathes, &c. The currents in the various circuits are measured by the fall of potential along ½in. copper rods connected with the switchboard. A sliding commutator enables any one of nine circuits to be connected to a voltmeter which requires 30 millivolts for a full scale deflection. There are two scales, one reading to 400 and the other to 80 amperes. The voltmeter is also fitted with a similar sliding commutator for measuring voltage. The scales are transparent and illuminated from behind, enabling the indications to be read at a considerable distance off.

The London County Council and the Telephone Protection Clauses.—At the meeting of the London County Council last week the Parliamentary Committee reported as follows :—We understand that a Joint Committee of both Houses is to be appointed to consider the subject of electric traction. There have been several discussions before the Board of Trade and Committees of Parliament as to whether any, and, if so, what form of protection should be given to the Telephone Company in the case of Bills authorising use of electricity either for lighting purposes or for motive power. It appears to be admitted that telephone wires constructed and worked on the principle commonly followed by the National Telephone Company are liable to be interfered with by induction as a result of the use of electricity for other purposes in the neighbourhood. The Telephone Company claim in such cases a clause, which, while reserving their position, would place those using electricity for other purposes under considerable obligations in order to provide against possible induction. The decisions of the Board of Trade and of the Committees have varied, and the appointment of a Select Committee to consider the whole question has become necessary, and as the Council is interested in the matter in regard to electric lighting, and possibly may be hereafter in regard to tramways which it may be desired to work by electricity, we recommend that the Council do give instructions that it be represented before the Joint Committee. The recommendation was adopted.

The "Hodgkins Fund" Prizes.—In October, 1891, Mr. Thomas George Hodgkins, of Setauket, New York, made a donation to the Smithsonian Institution, the income from a part of which was to be devoted "to the increase and diffusion of more exact knowledge in regard to the nature and properties of atmospheric air in connection with the welfare of man." The Smithsonian Institution now announces the following prizes to be awarded if satisfactory papers be offered :—1. A prize of $10,000 for a treatise embodying some new and important discovery in regard to the nature or properties of atmospheric air. 2. A prize of $2,000 for the most satisfactory essay upon—(*a*) The known properties of atmospheric air considered in their relationships to research in every department of natural science, and the importance of a study of the atmosphere considered in view of these relationships; (*b*) The proper direction of future research in connection with the imperfections of our knowledge of atmospheric air, and of the connections of that knowledge with other sciences. 3. A prize of $1,000 for the best popular treatise upon atmospheric air, its properties and relationships (including those to hygiene, physical and mental). 4. A medal will be established, under the name of the Hodgkins Medal of the Smithsonian Institution, which will be awarded annually or biennially, for important contributions to our knowledge of the nature and properties of atmospheric air, or for practical applications of our existing knowledge of them to the welfare of mankind. The treatises may be written in English, French, German, or Italian, and should be sent to the secretary of the Smithsonian Institution, Washington, before July 1, 1894, except those in competition for the first prize, the sending of which may be delayed until December 31, 1894. It is probable that special grants of money may be made to specialists engaged in original investigation upon atmospheric air and its properties.

ELECTROMAGNETIC THEORY.—L.

BY OLIVER HEAVISIDE.

(Continued from page 7.)

§ 200. In the consideration of the transmission of waves along wires, especially, of course, in practical calculations, it is more convenient to employ the line-integrals of the electric and magnetic forces as variables rather than these forces themselves. This transformation of variables involves other necessary transformations, and the connection between the old quantities, suitable for waves in general, and the new, should be thoroughly understood, if something more than a superficial knowledge of the subject be desired.

Thus, commencing with a circuit consisting of a pair of parallel straight conducting tubes, of no resistance in the first place, take for reference any plane which crosses the tubes perpendicularly. It is the plane of the wave at the place, and the lines of electric and magnetic force lie in it, the former starting from one (the positive) and ending upon the other (the negative) tube, the latter passing between and round them. These lines always cross one another perpendicularly, but their distribution in the plane may be varied by changing the size and form of section of the tubes by the plane and the distance of separation. Now there is no axial magnetic induction—that is, induction parallel to the tubes. Nor is there any tangential component of electric force on the surface of the tubes. It follows, by the second circuital law, that the line-integral of the electric force from one tube to the other is the same by any path in the reference plane. It is not the same by any path with the same terminations if we depart from the reference plane, but that is not yet in question. Call this constant line-integral V. It is the transverse voltage. In another form we may say that the circuitation of the electric force in the reference plane is zero.

Next consider the magnetic force. Its circuitation is also zero in the reference plane, provided the one tube or the other is *not* embraced, because there is no axial electric current in the dielectric. But when a tube is embraced the circuitation is finite. Call this quantity C. It is "the current" in the tubes, or, at any rate, is the measure thereof, and is positive for one tube and negative for the other. These two quantities, V and C, the transverse voltage and the current, are the new variables. They are as definite as **E** and **H** themselves in a given part of the reference plane under the circumstances.

Next, as regards the fluxes, displacement and induction. Introduce a second reference plane parallel to the first and at unit distance in advance of it along the tubes. Anywhere between the planes we have $\mathbf{D}=c\mathbf{E}$, where **E** and **D** vary according to position. Now, as we substitute the complete voltage for **E**, so we should substitute the complete displacement for **D**. The complete displacement is the whole amount leaving the positive and ending upon the negative tube, between the reference planes. That is, it is the "charge" per unit length of the tubes, say Q. As **D** is a constant multiple of **E**, so is Q a constant multiple of V. Say $Q=SV$. This S is the permittance of the dielectric, per unit length axially. It is proportional to c, the permittivity, but of course involves the geometrical data (brought in by the tubes) as well.

Similarly, we have $\mathbf{B}=\mu\mathbf{H}$ everywhere between the reference planes, **H** and **B** varying from place to place. But if we substitute the complete circuitation of **H**, we should also substitute the complete integral of **B**. This means the total flux of induction passing between and round the tubes, between the reference planes. Call it P. It is the magnetic momentum per unit length axially. As **B** is a constant multiple of **H**, so is P a constant multiple of C. Thus $P=LC$, where L is the inductance per unit length axially. This L varies as the inductivity μ, and involves the geometrical data.

In virtue of the relation $\mu cv^2=1$, the inductance and permittance are reciprocally related. Thus, $LSv^2=1$. Since v is constant, it might appear that the inductance was merely the reciprocal of the permittance, or the elastance, with a constant multiplier, only to be changed when the dielectric is changed. But there is much more in it than this. Different physical ideas and effects are conditioned by inductance and permittance. Inductance and inductivity involve inertia, whilst permittance and permittivity involve compliancy or elastic yielding.

Observe that P and Q are analogous, being the total magnetic and electric fluxes, whilst V and C are also analogous, the voltage and gaussage respectively. So the ratios L and S are also strictly analogous, in spite of their quantitative reciprocality. They are both made up similarly to conductance, only in the case of permittance it is reckoned across the dielectric from tube to tube, and in the case of inductance round and between the tubes—that is, the magnetic circuit is closed, and the electric circuit unclosed. There are other ways of setting out the connections, but the above way brings out the analogies between the electric and magnetic sides in a complete manner. The quantity C may be quite differently regarded when the magnetic field penetrates into the substance of a tube (then to be of finite conductance), viz., as the total flux of conduction current, or sometimes of displacement current as well, in a tube. But the above method is independent of the penetration, holding good whether there is penetration or not, saving small corrections due to the waves not being quite plane. The magnetic view of C, as the gaussage, is also the nearest to experimental electrical knowledge. The other view is darker, because we cannot really go inside metals and observe what is going on there, or the forces in action. They must be inferential in a greater degree than the external actions.

The electric energy per unit volume being $\frac{1}{2}\mathbf{ED}$ or $\frac{1}{2}cE^2$, when this is summed up throughout the whole slice of the medium contained between the reference planes at unit distance apart, we obtain the amount $\frac{1}{2}VQ$ or $\frac{1}{2}SV^2$, which is a therefore the electric energy per unit of length axially.

Similarly, the magnetic energy density $\frac{1}{2}\mathbf{HB}$ or $\frac{1}{2}\mu H^2$, when summed up throughout the slice, amounts to $\frac{1}{2}CP$ or $\frac{1}{2}LC^2$. The reader should, in all these transformations, compare the transformed expressions with the original, and note the proper correspondences. It is all in rational units of course, to avoid that unmitigated nuisance, the 4π factor of the present B.A. units.

The density of the flux of energy, which is the vector product of **E** and **H** in general, is of amount simply EH when the forces are perpendicular, as at present. When this is summed up over the reference plane, the result is VC, the product of the voltage and current. The flux of energy is parallel to the guiding tubes, and EH is the amount for a tube in the dielectric of unit section, whilst VC is the total flux of energy.

The relation $E=\mu vH$, or, which means the same, $H=cvE$, which obtains in a pure electromagnetic wave, becomes converted to $V=LvC$, or $C=SvV$. We see that Lv is of the dimensions of electric resistance, and Sv of electric conductance. Similarly, because V and C are the line-integrals of **E** and **H**, we see that μv is of the dimensions of resistance, and cv of conductance. The activity product VC is what engineers have a good deal to do with, now that "electrical energy," or energy which has been conveyed by electromagnetic means, is a marketable commodity. However mysterious energy (and its flux) may be in some of its theoretical aspects, there must be something in it, because it is convertible into dollars, the ultimate official measure of value.

§ 201. Now, still under the limitation that the guiding tubes have no resistance, and that the dielectric has no conductance, consider the special forms assumed by the circuital laws. These are, in general,

$$\text{curl}\,\mathbf{H}=c\dot{\mathbf{E}}, \quad \ldots\ldots\ldots \quad (1)$$

$$-\text{curl}\,\mathbf{E}=\mu\dot{\mathbf{H}}. \quad \ldots\ldots\ldots \quad (2)$$

Now, in applying these to our plane waves, we may observe at the beginning that **E** and **H** and their time-variations are in the reference plane, and have no axial components. So the only variations concerned in the operator "curl" are such as occur axially, or parallel to the guides. Let x be distance along them, then the circuital laws become

$$-\frac{d\mathrm{H}}{dx}=c\dot{\mathrm{E}}, \quad \ldots\ldots\ldots \quad (3)$$

$$-\frac{d\mathrm{E}}{dx}=\mu\dot{\mathrm{H}}, \quad \ldots\ldots\ldots \quad (4)$$

Digitized by Google

which apply anywhere in the reference plane. Transforming to V and C, we obtain

$$-\frac{dC}{dx}=S\dot{V}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

$$-\frac{dV}{dx}=L\dot{C}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (6)$$

By (3) and (4) we see that the space-variation of H is the electric-current density, and the space-variation of E the magnetic-current density in the dielectric. By (5) and (6) we express the same truths for the totals concerned.

We may see the meaning of (5) thus. Draw a closed line in the reference plane on and embracing the positive guiding tube. The circuitation of **H** there is the total surface current C. Let the closed line be shifted to the next reference plane at unit distance forward. Then $-dC/dx$ is the amount by which C decreases during the shift, and (5) tells us that it is equivalently represented by the time-rate of increase of the charge on the tube between the reference planes, or the rate of increase of the total displacement outward. This process may be applied to any closed line in the reference plane, provided it embraces the tube. When it is shifted bodily forward through unit distance to the next reference plane, the amount by which the circuitation of **H**, that is, C, decreases from the first to the second position measures the displacement current through the strip of the cylinder swept out by the closed line. This is the time-rate of increase of the charge per unit length of the tubes, and is the total transverse current from one tube to the other.

The meaning of (6) requires a somewhat different, though analogous, elucidation. Join the tubes by any line in the first reference plane. The line integral of **E** along it is V, the transverse voltage. Shift the line bodily along the tubes to the next reference plane. The transverse voltage becomes $V+dV/dx$, still reckoned from the positive tube to the negative. But if we join the two starting points on the positive tube together, and likewise the ending points on the negative tube, we make a complete circuit, having two transverse sides and two axial sides. Now reckon up the voltage in this circuit. The axial portions contribute nothing, because the electric force is perpendicular to them. The voltage required is, therefore, simply the difference in the values of the transverse voltage in the other two sides, or dV/dx. By the second circuital law, it is also measured by the rate of decrease of induction through the circuit, that is, by $-L\dot{C}$. Whence follows equation (6).

The reader who is acquainted with the (at present) more "classical" method of treating the electromagnetic field in terms of the vector and scalar potentials cannot fail to be impressed by the difference of procedure and of ideas involved. In the present method we are, from first to last, in contact with those quantities which are believed to have physical significance, instead of with mathematical functions of an essentially indeterminate nature, and also with the laws connecting them in their simplest form. Notice that V is not the difference of potential in general. It sometimes degenerates to difference of potential, viz., in a perfectly steady state. But when the state changes, we cannot express matters in terms of an electric potential.

Now, still keeping the guiding tubes perfectly conducting, let the medium in which they are immersed be slightly conducting. The electric-current density, which was $c\dot{\mathbf{E}}$ before, now becomes $k\mathbf{E}+c\dot{\mathbf{E}}$, where the additional $k\mathbf{E}$ is the conduction-current density. Along with this there is waste of energy at the rate kE^2 per unit volume. This waste of energy may also be regarded as a storage of energy, viz., as heat in the medium. But as it is not recoverable by the same means (reversed) which stored it, it is virtually wasted, and we have no further concern with it.

We have next to consider the total waste in the slice of the medium between the two reference planes, in terms of the transverse voltage. It sums up to KV^2, where K is the transverse conductance of the medium per unit length axially. This is proportional to the conductivity k, and involves geometrical data in the same way as the transverse permittance, as may be readily seen without symbolical proof, on considering that the conduction-currrent lines and the displacement lines are similarly distributed, whilst both are controlled by the transverse voltage. In fact, the conduction-current density $k\mathbf{E}$ sums up to KV, the complete transverse conduction-current, in the same way as the displacement density $c\mathbf{E}$ sums up to the total transverse displacement SV, in terms of the permittance and voltage.

The first circuital law (1) becomes changed to

$$\text{curl}\,\mathbf{H}=k\mathbf{E}+c\dot{\mathbf{E}}, \quad . \quad . \quad . \quad . \quad . \quad (7)$$

by the addition of the conduction current. And its modified form (3) for our plane waves becomes

$$-\frac{dH}{dx}=kE+c\dot{E}; \quad . \quad . \quad . \quad . \quad . \quad (8)$$

whilst in terms of the new variables, voltage and gaussage, we have this extended form of the equation (5),

$$-\frac{dC}{dx}=KV+S\dot{V}. \quad . \quad . \quad . \quad . \quad . \quad (9)$$

Next, let the medium become magnetically conductive as well, no other change being made. The conduction-current density is $g\mathbf{H}$, and its distribution resembles that of the induction itself, whilst its amount is controlled by the quantity C, the gaussage. The total magnetic-conduction current may therefore, be represented by RC, where R is the magnetic conductance, which varies as the magnetic conductivity g, and involves the geometrical data in the same manner as the inductance does.

Similarly, the rate of waste of energy due to the magnetic conductivity is gH^2 per unit volume, and the total rate of waste in the slice of the medium between the two reference planes amounts to RC^2 correspondingly.

Finally, the effect of the magnetic conductivity is to turn the second circuital law from the elementary form (2) to

$$-\text{curl}\,\mathbf{E}=g\mathbf{H}+\mu\dot{\mathbf{H}}, \quad . \quad . \quad . \quad . \quad (10)$$

and, correspondingly, the special form (4) for our plane waves becomes turned to

$$-\frac{dE}{dx}=gH+\mu\dot{H}. \quad . \quad . \quad . \quad . \quad . \quad (11)$$

This, in terms of V and C, is equivalent to

$$-\frac{dV}{dx}=RC+L\dot{C}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (12)$$

which is the proper companion to the equation (9) expressing the first circuital law. These equations (9) and (12) are the practical working equations.

We have already remarked that the structure of the electric permittance and conductance are similar. From this it follows that the time-constant c/k is identically represented by S/K. Similarly, the time-constant μ/g is identical with L/R.

The density of the flux of energy is with the two conductivities, still represented by the vector product of **E** and **H**, and therefore the total flux is still the activity product VC. To corroborate this statement, and at the same time show the dynamical consistency of the system, consider that if the quantity VC is really the flux of energy across a reference plane, the excess of its value at one plane over that at a second plane further on at the same moment represents the rate of storage of energy between the planes. Therefore, the rate of decrease of VC with x is the rate of storage between two reference planes at unit distance apart. Now,

$$-\frac{d}{dx}(VC)=-V\frac{dC}{dx}-C\frac{dV}{dx}, \quad . \quad . \quad . \quad . \quad (13)$$

On the right side use the circuital equations (9) and (12), and it becomes

$$V(KV+S\dot{V})+C(RC+L\dot{C}), \quad . \quad . \quad (14)$$

or, which is the same,

$$KV^2+RC^2+\frac{d}{dt}(\tfrac{1}{2}SV^2+\tfrac{1}{2}LC^2) \quad . \quad . \quad (15)$$

By the previous, the first term is the total electric waste, the second is the total magnetic waste, the third is the increase of

Digitized by Google

total electric energy, and the fourth is the increase of total magnetic energy, per unit of time, between the two reference planes. This proves our proposition, with a reservation to be understood concerning the circuital indeterminateness of the flux of energy. There is, therefore, no indistinctness anywhere, or inconsistency. We have now to show in what manner the above is affected by the resistance, &c., of the guides.

(To be continued.)

THE CHICAGO EXHIBITION INTRAMURAL ELECTRIC RAILWAY.

We take the following interesting particulars with regard to the elevated electric railway in the Exhibition grounds at Chicago from a long and well-illustrated account appearing in the *Electrical World* of May 6th :—

The Western Dummy Railroad Company, says our contemporary, obtained the contract on a basis of 25 per cent. of the gross receipts and a 10 cent. fare.

The line consists of close on three miles of double track. There are ten stations in all, and at each of these, with a few exceptions, the track is caused to rise, thus serving as a check to approaching trains and an assistance to those departing. Otherwise the track is essentially level, varying from that to 0·42 per cent and 1·5 per cent. grades, and in one short stretch reaching 2 per cent. The curves at the terminals are short, viz., 100ft. radius, and the others vary between that and 2,000ft.

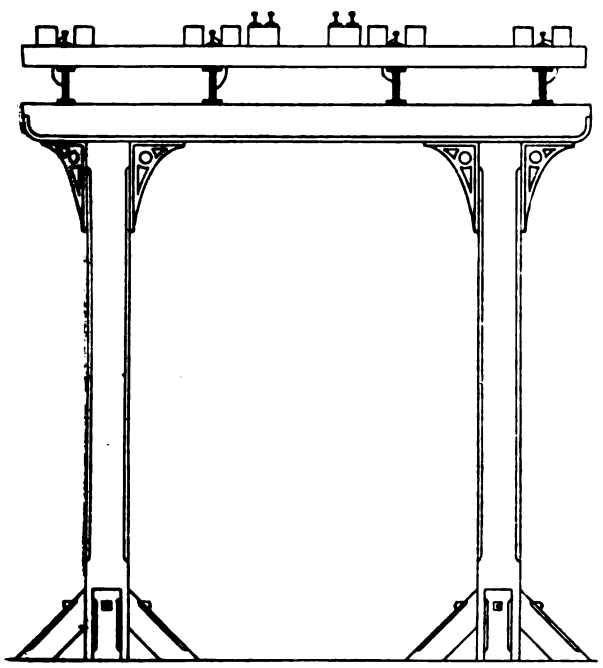

Fig. 1.—Section of Track, showing Electrical Connections.

Work was commenced early last autumn on the elevated structure, which is a doubled-tracked affair, supported for the most part by the 12 × 12 square sets of pine, and surmounted by I beams—two to the track. These latter are usually 25ft. in length, and are carefully bonded to furnish the main return for the current (*see* Fig. 1). This bonding consists of from two to five copper strips, according to the situation, each 2in. wide and $\frac{1}{16}$in. thick, riveted cold through holes in the web of the stringers that have been carefully reamed to afford good electrical contact. These rivets are of copper, $\frac{7}{8}$in. in diameter and 2in. long, and two of them are used in each bond. The outer strip of each bond is looped into an eye for the ready reception of the terminal of a conductor connecting with the track above. The conductors that are used for carrying the current to the motor cars are T rails of exactly similar design and weight (60lb. to the yard) as the track rails. They are laid parallel to the tracks, 18in. to one side and elevated so that their faces are about 12in. above the crossties. The wooden blocks supporting the working conductors serve as insulators. Parallel to the working conductor, and as close to it as possible, is another rail similarly elevated on blocks. This is the feeder, and extends along both trolley rails for about three-fifths of the distance from the power-house to the further terminus. These two lines of rails—the working conductor and the feeder—are laid so that their joints come together, and are bonded in similar manner to the track rails with the loops or eyes facing each other, and connection is made between the two by inserting into these eyes the two legs of a hairpin-shaped wire, and electrical connection insured

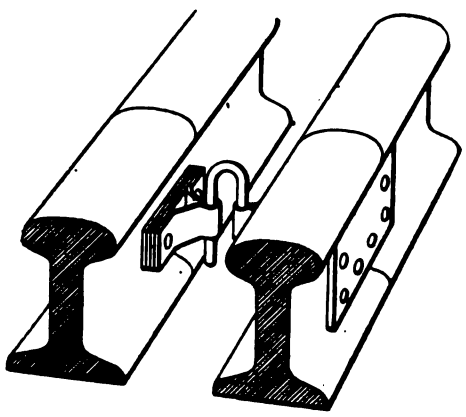

Fig. 2.—Feeder and Working Rail Connection.

by soldering (Fig. 2). The track rails are also bonded in similar manner, and each rail of each track is connected to the girder beneath by a wire which is soldered into this eye. Thus the four large girders form the electrical return for the current which passes from the wheels to the track.

The equipment consists of 15 trains of three open trailers and a motor car, together with three extra motor cars. Each of these cars is 50ft. in length. The trailers when loaded will weigh 22 tons and the motor cars 30 tons. Each motor car is equipped with four motors, one to each axle. These were specially built for the purpose by the General Electric Company, and are of the T.-H. 4-pole ironclad type. The armatures are Gramme ring with bar winding with three turns to

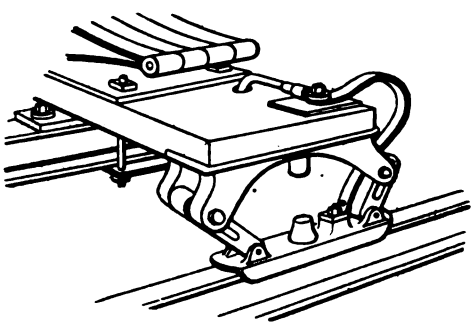

Fig. 3.—The Trolley.

the coil, and are cross-connected so as to require but two brushes—carbon being used. They are single reduction, so geared as to work at a maximum speed of 35 miles per hour, and are capable of an output of 133 H.P. with safety—thus giving a total capacity for each motor car of something over 500 H.P. The motors themselves weigh about 4,000lb.

On each motor car there are four trolleys or sliding contacts —two on each side. These are attached each to a heavy oak plank extending out from the centre of the trucks some 18in. beyond the wheels. They consist (*see* Fig. 3) of an iron frame with two arms, as shown in the cut, having pins which loosely hold two iron links, to which is attached the shoe proper. This is of cast iron, about 12in. long, and so shaped as to fit loosely upon the face of the rail. All of this portion of the trolley is carefully insulated from the truck, but electrical connection is made between the shoe and a binding post on top of the wooden support by means of a bundle of flexible copper strips. The

Digitized by Google

link connection permits of considerable vertical movement of the shoe, and also of the adjustment of the latter to the motion of the car in either a forward or backward direction. The first shoes made were of brass, and were cast with a lug on their upper side corresponding with another one on the iron support above. These were intended to form supports for a spiral spring in compression for the purpose of insuring better contact between the shoe and the track. Experiment, however, has shown that the weight of the shoe is sufficient for this purpose, and the spring has been discarded. Iron has also been substituted for brass as being cheaper and answering equally well.

The controlling appliances are located at the front end of the car in a compartment set aside for this purpose, the motive power of the regulating drums being compressed air. All the trains are fitted with air-brakes.

The power house consists of a boiler room 140ft. long and 60ft. wide, and an engine and dynamo room 140ft. by 87ft. In the former is located the bank of Babcock and Wilcox boilers, ten in number, rated at 300 H.P. each. These are fired by oil supplied through jets extending into the combustion chamber, fed by 2in. pipes connected with the tanks at the south boundary to the park. On the engine-room floor, which is raised some 10ft. above the boiler-room floor, are arranged, beginning at the east end, a Reynolds tandem compound Corliss engine, coupled to a direct 500-kilowatt multipolar generator. The armature of this machine overhangs the bearing of the shaft. Next comes a Hammond-Williams vertical engine, cross compound, driving a similar generator 500-kilowatt capacity, and capable of working up to 1,200 H.P. In the centre of the floor is the great 2,000-H.P. cross-compound Reynolds-Corliss engine, which operates a 1,500-kilowatt multipolar generator. This is direct connected. West of this stands a McIntosh and Seymour tandem compound engine, coupled direct to a 200-kilowatt multipolar generator, and at the west end of the building is located a tandem compound Greene engine, belted direct to a 500-kilowatt multipolar generator.

The great 2,000-H.P. generator, which is fairly entitled to the place of honour which it occupies in the centre of the building on account of its size, has another claim upon our attention from the manner of its construction. On account of its size, the different parts of which it is composed, after having been shaped at the various shops and foundries in which they were made, were shipped separately and put together for the first time in this building. The estimated weights of the parts are:—

	Tons.	cwt.
Weight of field magnet complete	35	14
Weight of armature	32	17
Weight of commutator	5	10
Total weight of dynamo	80	7

Some of the dimensions are as follows:—

Diameter of armature	10ft. 6in.
Face of armature	36¾in.
Diameter of commutator	7ft. 6in.

On account of the great difference between the internal and external diameters of the hub of the armature it was necessary to take precautions against fracture or warping due to shrinkage. The method employed was as follows:—The hub was cast with three slots at an angle of 120deg. with each other, extending radially so as to allow for a maximum contraction as the casting cooled. When all was cool these slots were filled with molten iron, thus making the hub solid, and a steel ring 7in. broad by 4in. deep was then shrunk on to a seat prepared for it, immediately surrounding the inner terminals of the slots.

The hub and shaft were shipped in one piece, and weighed, when received, 56 tons. The shaft itself is 25ft. long between centres, and 24in. in diameter. Its main bearing is 22in. in diameter and 42in. long. The hub, which was shrunk on to the shaft, supports at the end of its six heavy spokes a rim upon which are set 29 bars parallel to the shaft, each grooved longitudinally with a dovetailed slot, into which fit similar projections stamped into the inner edge of the sheets of sheet iron of which the armature core is built.

The armature core was built up of ordinary sheet iron 0·017in. thick, cut with lugs on the inner side for the slots before mentioned, and of such a length that nine of these sheets, set end to end, complete the circle and lap over just one-half a length. Each sheet has two dovetails on its inner side just corresponding in distance apart with the distance between the slots into which they are to slide. Thus, when the ninth segment is placed in position, the dovetail in its lapping portion takes into the same slot as the first dovetail of the first segment. Additional segments are added, with their shorter sides abutting, the segments of each circle lapping the joints in the preceding circle, and thus the armature core is built up spirally. The dovetails of each segment are introduced into the slots at one end, and the sheet is pushed along until in place. When a thickness of 3in. has been thus built up, a brass section 1in. thick with radial openings is slipped on, and the completed portion of the core tightly compressed. In this case, a large number of small hydraulic jacks were employed to force the sheets of iron into intimate contact. The brass plates are allowed to remain in position, the radial openings answering for ventilating ducts. Upon this another section is built in similar manner, and so on, until the required number of sections are completed. There are in this armature nine of these sections and eight ventilating sections, and 17,200 pieces of sheet iron, weighing 25 tons, were used in its construction. Next, the washers are put on. These consist of two large cast iron rings weighing four tons each, which have a lesser outside and inside diameter than the armature ring itself, and they are tied together by 29 tie-bolts 1½in. in diameter, by tightening the nuts on which the layers of sheet iron are strongly compressed. The tie-rods pass under the armature ring, but are not otherwise insulated from the armature core. In this armature the coils are not wound over the ring, but are embedded in the iron itself. For this purpose, the sheet iron, before it was sent to Chicago, had been stamped with slots near its outer circumference, so spaced relatively to the dovetails on each sheet that when they are placed in position the slots on succeeding layers register exactly. There are 348 of these slots. When first pressed together the edges of the sheet iron gave the interior surfaces of these slots a somewhat rough appearance. This had to be smoothed down, and for this purpose the file was brought into play. A 4-kilowatt Edison motor was belted to four filing machines, which consisted simply of four long files of the proper length and size, which were inserted in as many slots and given a reciprocrcating motion by means of cranks. All of these 348 slots have thus been filed smooth, and the face of the armature was also filed down by hand.

Each coil consists of two turns, each consisting of two copper strips in multiple. These strips are ¾in. wide by ¼in. thick, and are carefully insulated from each other by mica, and then wrapped together in mica and oiled linen tape. Before inserting these in the slots, channel-shaped tubes of mica were placed in the slots as a further insulation between the conductors and the core, and then the two compound conductors were introduced, radially to each other, and, finally, outside of these strips of wood were tightly driven in, fixing the conductors rigidly in place.

The equipment and operation of this road, says the *Electrical World*, has a much greater significance than its mere size would indicate, for it is practically the first electrical equipment of an elevated road that has ever been made.

ON THE DISSIPATION OF ELECTRICITY BY DIFFUSED LIGHT AND IN THE DARK.*

BY EDOUARD BRANLY.

My previous experiments on the dissipation of electricity, some of which have been published in the *Comptes Rendus*, having led me to think that the conductivity of gases and especially of atmospheric air depended less on their individual properties than on the conducting surfaces between which they were interposed, I sought for fresh proofs. I wish in the present communication to call attention to the definite facts, out of many experiments the interpretation of which is still doubtful, which seem to me to be of special interest. The observations were made with a gold-lea

* From the *Comptes Rendus*, Vol. CXVI., No. 15.

Digitized by Google

electroscope, the insulated rod of which is screwed on to the block of a pneumatic machine. Upon this block are placed as desired the bell-jars or the conducting boxes. The gold-leaf is enclosed in a completely metallic cage. The insulating material I use is roll sulphur, which is easy to work and possesses, in addition to exceptional insulating qualities, the advantage of being proof against atmospheric influences, thus rendering unnecessary the taking of special precautions. In order to obtain a constant charge, I employ two-fluid cells (platinum, sulphate-protoxide of mercury, zinc, sulphate of zinc) which I described in *La Lumière Electrique* of May 16, 1891. The cells are divided into groups of 25, most of which have been in use several years.

Dissipation of the Negative Charge on Aluminium placed in Diffused Light.

A disc of aluminium, 15cms. in diameter, was placed on the knob of the electroscope in a well-lighted room, and was connected to the negative pole of a battery of 300 cells. A well-polished disc, if it has been polished several days previous, behaves like any other metal, polished or unpolished. It shows a loss of charge, sensibly equal for the two signs, very slow and independent of the light. But if the disc of aluminium has been energetically and freshly polished (polished by turns with emery paper and a drop of essence of turpentine), the fall of the gold leaf becomes rapid even under diffused light. The total separation of the gold leaves being 80 divisions on the micrometer of the inspecting microscope, the fall in 30 seconds may amount to half this, that is to say, 40 or even 45 divisions out of 80. The discharge is soon complete. The active light was, in this case, the light which had traversed the windows of the laboratory. A glass vessel, even if tinted an orange yellow, may be placed on the supporting block and cover the disc without causing the discharge to cease ; it is only slowed down. It follows from this that the most refrangible rays are not the only active ones. The dissipation decreases the further one goes from the time when the disc was polished.

The following are a few figures relating to two consecutive tests, the observed fall of the gold leaf being expressed in micrometer divisions (total separation = 80 divisions).

Freshly polished aluminium disc.	Fall in 60 seconds.
Under the yellow glass vessel	4
In the open	25
Under the yellow glass vessel	3
In the open	21
,, ,, ,, (after 35 minutes)	9

The same disc was then repolished with the same care as before, and its sensitiveness was increased. Generally speaking, it increased to a certain limit, after which more polishing had no effect.

	Fall in 30 seconds.
In the open	27
Under yellow glass	3
In the open (after 35 minutes under glass)	8

When the disc is covered by a metallic net with very small meshes, a loss due to the light that traverses these meshes is very clearly traceable. Perfectly-polished zinc in diffused light showed a loss equal to 15 micrometer divisions in 30 seconds (aluminium exceeding 45). A freshly-polished aluminium disc exposed to a blue sky through an open window, but sheltered from the direct solar rays, lost all its charge in seven seconds ; the zinc disc required 20 seconds, and one of cadmium 75 seconds. The discharge was naturally still more rapid under the direct action of the sun's rays. It also occurred with the light from the clouds.

When a disc of aluminium connected to the earth, freshly polished and illuminated by daylight, is placed in front of the knob of a *positively* charged electroscope, the electroscope is rapidly discharged. Copper, tin, brass cause insignificant losses.

Dissipation of both Positive and Negative Charges on Bismuth ed in the Dark.

As I have already pointed out, metals, whether polished or not, exhibit in the dark and in the open a small loss of charge independent of that caused by light, and which is shown on the electroscope previously used by a fall of one to two divisions in ten or fifteen minutes. When the discs are covered with a metallic box the loss of charge is almost zero for the same interval of time.

A disc of bismuth 15cms. in diameter, covered with a metallic box and charged positively or negatively, showed a constant loss of 12 micrometer divisions in ten minutes, in dry or wet air, and whatever the age or degree of polish. Bismuth is the only metal with which I have observed this noteworthy loss in the dark. I should add that out of the five bismuth discs I possess only two exhibit this phenomenon. However, whatever may be the investigations that it will be necessary to carry out before we can know the cause of this peculiarity, the existence of the special influence of the nature of the surface upon the dissipation of electricity even in the dark is made manifest.

THERMAL RADIATION IN ABSOLUTE MEASURE.*

BY J. T. BOTTOMLEY, F.R.S.

The Paper contains an account of an experimental investigation by the author in continuation of researches on the same subject which have been already published (Roy. Soc. *Proc.*, 1884, and *Phil. Trans.*, 1887). In the earlier experiments metal wires heated by an electric current were used. The loss of heat from a heated body, however, depends to some extent on the form and dimensions of the body, and it seemed important to experiment on the loss of heat from bodies differing in form from the wires already used, and larger in dimensions. Accordindgly, two copper globes used by Mr. D. Macfarlane in 1872 (Roy. Soc. *Proc.*, 1872, p. 93) were employed for a new series of experiments.

After preliminary experiments (using the same enclosure which Macfarlane employed, and with the surfaces of Macfarlane's globes prepared in four different ways) new apparatus was constructed, the object being to experiment both with full air pressure and with different amounts of exhaustion of the air, and Macfarlane's enclosure being unsuitable for this purpose.

In the arrangement adopted, the heated globes were hung at the centre of a hollow metallic sphere, which was connected with the Sprengel pump and surrounded with cold water, and were allowed to cool. The temperature of the cooling globe was read off at equal intervals of time by means of a thermo-electric junction ; and from these readings the absolute loss of heat per unit of cooling surface, per unit difference of temperatures of surface and surroundings per unit of time is calculated.

The details of the apparatus and method of experimenting are given in the Paper. It is enough to say here that the globes were used with their surfaces in two different conditions :—(1) Thinly coated with lamp-black, and (2) silvered and brightly polished ; and in both conditions the absolute loss of heat, both in air and in vacuum, more or less complete, was determined. The tables and curves attached to the Paper give the details of the results.

To quote one or two examples :—With the sooted surface a total loss of heat by convection and radiation of $3{\cdot}42 \times 10^{-4}$ C.G.S. units per square centimetre, per second, per 1°C. of difference of temperatures of globe and surroundings, was observed with a difference of temperatures of 100°C., and with the surroundings at about 14°C. Under similar circumstances the radiation in vacuum of $\frac{1}{2}$M (half-a-millionth of atmospheric pressure of non-collapsible gas) was about $1{\cdot}40 \times 10^{-4}$.

Taking a silvered and brightly-polished surface under the same circumstances, the loss in full air was $2{\cdot}30 \times 10^{-4}$ C.G.S. ; and with the highest vacuum and brightest polish obtained, it was reduced $1{\cdot}80 \times 10^{-5}$ with in this case a difference of temperatures of 180°C. The loss with 100°C. difference would be considerably less, but is not known experimentally at present.

The author returns thanks to Mr. James H. Gray, M.A., B.Sc., for excellent assistance given ; and expresses himself most deeply indebted, both for assistance in experimenting and calculating of the results, and for most valuable and ingenious aid of various kinds during the course of this work, to his friend, Mr. A. Tanakadate, now Professor in Tokio, Japan.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, May 26th.

PHYSICAL SOCIETY.

5 p.m. Ordinary Meeting. Papers to be read and discussed : (1) Discussion upon Dr. Lodge's Paper—"The Foundations of Dynamics" ; (2) "A New Photometer," by A. P. Trotter ; (3) "Notes on Photometry," by Prof. S. P. Thompson, F.R.S. ; (4) "Exhibition of a Vibrating Bar," by C. J. Woodward.

MONDAY, May 29th.

UNIVERSITY COLLEGE, LONDON.

3:30 p.m. Opening of the new Engineering and Electrical Laboratories by the Duke of Connaught, K.G.

TUESDAY, May 30th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Annual General Meeting of corporate members only, to receive the Report of the Council, and to elect the Council and Auditors for the ensuing year.

THURSDAY, June 1st.

CHEMICAL SOCIETY.

8 p.m. Ordinary Meeting. Papers to be read.

FRIDAY, June 2nd.

ROYAL INSTITUTION.

9 p.m. Evening Discourse : "Study of Fluid Motion by means of Coloured Bands," by Prof. Osborne Reynolds, F.R.S.

* Abstract of Paper read before the Royal Society.

The Electrician.

(The Oldest Electrical Journal.)

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.

Editorial, Publishing, and Printing Offices :

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone No. 2714. Telegrams: "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street. London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed "Coutts and Co."*

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November. Old Back Numbers and Volumes of* "THE ELECTRICIAN" *are frequently wanted, and offers will be made by the Publisher therefor.*

Subscription Rates —The rates for Subscriptions to "THE ELECTRICIAN" are as follows :—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies :—

Other Countries	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Advertisement Rates, &c., forwarded on application to the Publisher

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 4.30 p.m. Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.*

"THE ELECTRICIAN" SERIES *at present consists of—*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.

VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free.

VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post-free.

The same in German, price 8s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING (1893). By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s 6d., post free.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. [*Nearly ready.*

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. *Nearly ready.*

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. [*Nearly ready.*

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*In preparation.*

ELECTRICITY AS A MOTIVE POWER. By A. T. SNELL. [*In preparation.*

THE INCANDESCENT LAMP: Its Manufacture and Use. [*In preparation.*

Now Ready, in Two Volumes. Prospectuses Free.

"THE ELECTRICIAN" PRIMERS. *Fully Illustrated.*

Price: Stout paper covers, 2s., post free, 2s. 2d. each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

Volume XXX. of "THE ELECTRICIAN," price 12/6; post free, 13/6; abroad carriage extra.

Cases for binding Volume XXX., price 2/0, post free, 2/3.

The Publisher is able to supply a set of the Volumes of "THE ELECTRICIAN" complete except for three Nos. Price on application.

ELECTROLYTIC METERS.

Notwithstanding the fact that the voltametric is the most direct method of metering current, it is more usual, for commercial purposes, to employ some form of instrument constructed either on the principle that electromagnetic forces quicken or slow the time of a clock, or retard the motion of an electromotor by forces proportional to its velocity, such forces being fluid friction when the motion is very slow and the resistance due to Foucault currents. Now, as these electromagnetic meters must themselves be calibrated by means of a voltameter, it seems strange, at first sight, that electro-chemical devices are not more largely employed. There are many methods which appear in the laboratory to possess the elements of a decided commercial success, but, nevertheless, hang fire when they cross the threshold of the testing-room. It does not by any means follow that these methods are too delicate for every-day use, or that they require an undue amount of skilled attention. As often as not, their field of commercial utility is restricted by reason of the very different aspect certain little precautions or attentions come to wear when they are needed, not by one or two experimental apparatus situated in a laboratory and tended by a cohort of energetic students, but by several hundreds of pieces of mechanism placed here, there and everywhere, and exposed to wide variations of temperature and no little rough usage. It is, therefore, desirable to discover whether the small commercial favour with which voltameters have met is due to prejudice, or to inherent defects in electro-chemical methods of measurement when subjected to the exacting conditions of ordinary use.

The early form of voltameter, in which the amount of oxygen or hydrogen, or of the mixed gases given off on the passage of the current through an acidified solution, is taken as a measure of the energy expended, is obviously unsuited to

Digitized by Google

practical requirements. A large current is required to produce any visible decomposition in a reasonable time; both the temperature and the pressure must be known accurately before the watts can be calculated; and, further, McLeod and others have shown that the theoretical amount of oxygen is not given off, the loss being a variable quantity. These drawbacks, however, do not prevent the use of modified forms of the instrument in German laboratories for electrolytic purposes. Another disadvantage is that, since the amount of chemical action produced in a given time by a certain current is independent of the shape or size of the instrument, it is impossible to increase its sensibility. On the other hand, this disadvantage is not of importance when we deal with the large currents now use industrially. In the Edison meter, invented first by J. T. Sprague, but brought out by Edison, the depositing cell is put as a shunt on the main current, and, in its early form, a continuous current passing between two balanced plates suspended in a solution of copper sulphate decomposed one plate and deposited copper on the other, causing it to gain in weight and tip over the balanced beam. This action registered a unit on a counting mechanism, and reversed the direction of the current, so that the lighter plate received the deposit. In practice it was found that the make and break, as necessitated by the reversals of the current, led to endless trouble, and the ingenious method of counting had to be abandoned. In the improved meter zinc is the metal employed and sulphate of zinc the solution. The current always goes in one direction, and fresh plates are inserted as they wear away. Theoretically this meter is not accurate, because the relation between the total current and that which has passed through the meter can never be known accurately, but in practice it has given satisfaction. MM. Desruelles and Chauvin have recently brought out a modification of the original Edison meter, in which the whole of the current passes through the instrument instead of only a portion. In the Grassot meter the anode is a silver wire, while the cathode is zinc and the solution nitrate of silver. As the anode loses weight the cathode descends and pulls round a drum actuating a train of clock-wheels and indicating dials. So much for electrolytic meters, proposed, and in use.

Turning now to the work which has been done in laboratories, we find that for purposes of accurate standardisation T. Gray recommends the silver nitrate voltameter used by Kohlrausch, Lord Rayleigh, and Mrs. Sidgwick, but prefers very thin vertical parallel plates to the bowl method recommended by Poggendorff and adopted by the latter. For large currents of from 10 to 100 amperes the use of a silver voltameter is prohibited by the expense, and Gray found that although, as stated by Lord Rayleigh and Dr. Gore, care had to be taken in drying the cathodes, owing to the tendency of the copper to oxidise in the air and to the cathode losing weight if left standing in the liquid, the error need never exceed one-tenth per cent. He recommended the use of anodes having a surface of 50 sq. cm. per ampere, and found that if the current density at the anode exceeded $\frac{1}{40}$ ampere per square centimetre the current was apt to be variable and might almost stop completely even when an electromotive force of 25 volts was used. This phenomenon depended on the density of the solution and the current, and in some cases, after a few minutes' cessation, the current nearly regained its former value, gases being freely given off. Gray also found that the temperature had a very marked effect on the weight of copper deposited, although the temperatures which would ordinarily be experienced in this climate had not. In his first Paper he recommended the use of ordinary pure copper sulphate, or that with only the addition of a trace of free acid; in his second Paper the addition of 1 per cent. of sulphuric acid was recommended. J. Vanni, repeating Gray's experiments, confirmed his results as regards the effect of the size of the anode, and recommended the use of a copper sulphate solution containing merely a trace of free acid; and Oettel, as we noted in our last issue, has again confirmed these results, and shown that not only is the *size* of the anode a factor to be taken into account, but also its *nature*, inoxidisable metals like platinum causing a greater deficit in the amount of copper deposited than occurs with copper. Oettel has further shown that the addition of an oxidisable body to the electrolyte *decreases* the loss of copper, so that there can be little doubt that the loss of copper is occasioned by the formation of some highly oxidised body in the electrolyte, and that this body is the persulphate of copper described by Marshall. It is noteworthy in this connection that Gray mentions the deposition on the anodes in some of his experiments of a brown powder, and that electrolysed copper sulphate—as was mentioned at the Cardiff meeting of the British Association—when *at rest* deposits copper on reducing substances, such as carbon. These facts and others of a similar nature, interesting and valuable as they are to the electro-chemist, do not tend to enhance the probability of electrolytic meters receiving the *imprimatur* of the Board of Trade, and serve to explain the absence of such apparatus from houses supplied by statutory companies.

REVIEWS.

A Handbook of Electrical Testing. By H. R. Kempe. Fifth Edition. (London: E. and F. N. Spon.)

The particular feature or features which constitute a handbook are as difficult to determine as those which constitute an engineering pocket-book, if one is to be guided by the examples of either which one meets with. Is a handbook a small, portable volume easily carried in the hand, or is it a ponderous tome? The work before us started as the one, and has passed through five expanding stages till it has become the other. Is a handbook a volume which contains something handy, and which one may want on the spur of the moment in practical work? The work before us consists chiefly of that which one would never want in practical work, and much that would be of little use even to a theorist. Then, again, what is electrical testing? Since the first edition of this book made its appearance, electrical work has come to be something more than telegraphy, and electrical testing something more than "loop tests," "bridge tests," "Mance's methods," *et hoc genus omne*. Yet there is in the book no sign of this great change; it remains purely telegraphic, and, for the most part, submarine-telegraphic, and has nothing to say on the subject of the important heavy electrical tests which its title would lead one to demand from it. Obviously the book before us is a book for only one section of electrical engineering, and as such we will now consider it. In its 550 pages there is a matter of about 90 tests described, of which 43 relate specially to cable testing, and 27 of these to the localisation of faults in submarine cables. Of the remainder, a large proportion is devoted to tests on the E.M.F. of primary batteries, chiefly of low voltage, 10 of these tests being given. Besides these battery tests, there are a number of methods of measuring potentials, and the remaining portion of the work is devoted principally to simple tests of galvanometer resistance, capacity and ordinary resistances. It will be seen, then, that this volume of 550 pages does not cover any very large extent of ground. This is explained by the altogether disproportionate amount of space—if we mistake not the purpose of a book of this sort—which is devoted to "proofs" of tests, and to elaborate mathematical discussions of the

Digitized by Google

"probable error" and "best conditions" for each test. Let it not be supposed that we despise the proof of a test, nor that we would not be as anxious as anyone else to know the probable error and the best conditions in making it. The point lies in the waste of time and space which arises from the inordinate elaboration and monotonous repetition of these things. Would it not be much better, would it not save a great deal of space, if a separate short chapter on the *principles* of determining these things were given once for all the tests, the rest being left to the wit of the reader? A student who has so far advanced in mathematical learning as to be able to follow Mr. Kempe's repeated proofs would have no difficulty—nay, would find it easier—to adapt a general discussion to each particular case he might require. Mr. Kempe's logic is tedious; it lacks that imagination which leaves something to be done by the reader; it prefers to build up a pile of special examples, rather than to evolve a neat and general proof. Referring now for a moment to details, we have been rather surprised to find no definitions of the legal standards of resistance and voltage in the book, the nearest approach being the definitions of Matthiessen's copper standard and of Clarke's cell. We should have thought, too, that in a work so largely devoted to matters concerning submarine cables, some reference would have been made to the much-discussed K R law, but we can find none.

Notwithstanding all its defects, this work probably meets the wants of a certain large section of electricians who are willing to ignore the useless matter in order to get the useful truths it contains. The book is accurate, and, as such, it is reliable. The pages after pages of tedious mathematics do not destroy one jot of the value of the short descriptions and accurate diagrams of the tests which it also contains. That the work has attained to its fifth edition and is now adopted by the Postal Telegraph Department makes it evident that it is a not unimportant factor in technical literature.

The Elements of Physics. By HENRY S. CARHART, M.A., and HORATIO N. CHUTE, M.S. (Boston: Allyn and Bacon.)

That well-known physical law—the law of the pendulum—has led the authors to produce this text-book of physical science. Not alone in the to-and-fro motion of a mass particle at the end of a string, or in the ebb and flow of the ocean tide, but in all the affairs of men, of nations, of the entire universe, can the operation of this law be seen. The stress and failure of each opposite extreme induces, in time, the adoption of the other, producing a ceaseless rhythmical oscillation between equally impracticable limits. Such is the law; and it operates on the curriculum of the physical laboratary. "A few years ago it seemed necessary to urge upon teachers the adoption of laboratory methods to illustrate the text-book," write the authors of this work; "it would now seem almost necessary to urge the use of a text-book to render intelligible the chaotic work of the laboratory." This view of the situation we completely endorse; and the remark is equally true of laboratories on this side of the Atlantic as of those in America. Time has shown the fallacy of setting each student to re-discover the laws of physics by actual experiment and observation in a laboratory. Life is not long enough for it. The true function of a physical laboratory is not to monopolise instruction, but to supplement the lectures, to instruct the student in the principles of inference from experiment, and in the handling of apparatus. The reaction against the old-fashioned "recitation" method has been more than complete, it has been severely overdone—the pendulum has travelled too far towards the opposite extreme. It is now swinging back again. One of the deplorable consequences of this last anti-phase has been the flood of text-books for students, which bids fair to carry the pendulum bob far into another impracticable region. This may be looked on as the *hysteresis* of the cycle—the purely wasted energy!

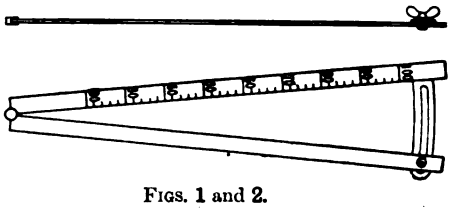
The particular contribution to this flood by the authors of the work before us is undoubtedly superior to the average. It forms a compendium of the elementary physical sciences, comprised within a volume by no means large, but which is composed of well-selected matter, written in a lucid style. The treatment is experimental and illustrative, rather than mathematical, although each chapter is supplemented by a list of problems to be worked out by the student. After the introductory chapter, the Mechanics of Solids are treated, the student being familiarised with force, energy, and matter. Chapter III., on the Mechanics of Fluids, is less satisfactory, the treatment being conventional, not to say antiquated. A short chapter on Heat follows. Magnetism and Electricity are dealt with next, in what is by far the longest chapter in the book. This part is a careful compilation; and, with the exception that we think the space devoted to the applications of electricity might have been more usefully disposed, we have no objection to it. In a small book covering so wide a field, it is rather a disproportionate arrangement to devote space to dynamos and the different kinds of magnet winding; and the book loses sight of itself where it strays into descriptions of motors, telegraphs, and telephone circuits. Chapter VI. deals with Sound, and contains some original simple experiments for illustrating the principles of that science. The last chapter, on Light, deals with the chief phenomena of visible radiation. On page 314, the mode of using the Bunsen photometer is incorrectly described. Instead of adjusting the grease spot till it becomes "invisible" or "is least conspicuous to one viewing it from a position in line with the three objects" (the two lights and the screen), it is not only customary but necessary to view it obliquely and at a definite angle. This is usually effected by means of inclined mirrors. The best adjustment is when the appearance of the grease spot is similar when viewed from both sides.

THE TAPER OF COMMUTATOR SECTIONS.

BY F. M. WEYMOUTH.

When the segments or bars for a commutator are cast, instead of being rolled, they require to be machined or filed on their sides before being put together. To secure accuracy in this operation, it is necessary that the parts be worked up to a gauge. In this manner the requisite exactness in both thickness and taper may be obtained. When, on the other hand, drawn copper is used, it is equally necessary to specify the exact taper in ordering, and generally to send a gauge, sample, or template to the manufacturer.

A very useful and simple gauge or tool was designed for this purpose and adopted in 1886 by Messrs. Goolden and Trotter. This instrument is illustrated on a reduced scale, in Figs. 1 and 2 herewith. There are two ways of stating



FIGS. 1 and 2.

the taper for a commutator segment or strip. One is to give the angle between the sloping sides, and the other is to describe the slope of one side in relation to the other side as a gradient of "one in so many." As a circle is divided into 360 degrees, the angle for a segment is, of course, arrived at by simply dividing the 360 by the number of segments, or "parts." Thus the angle of a strip for a "40 part" commutator will be 360/40 = 9degs. But it must be noted that this assumes the parts put together *without the insulation*. This point requires attention. It has to be borne in mind that the mica or other insulation between the segments, does *not* taper, but is of even thickness. Fig. 3 shows how all the strips of a commutator are made to fit in the first instance, *minus* the insulation; while Fig. 4 shows the same parts put together *with* the insulation. This latter at once increases the diameter; and it should be noted further, in this latter case, that the sides of the sections, if continued inwards, do not meet at the centre. Here, in fact, is demonstrated how great an effect on the ultimate diameter the insu-

Digitized by Google

lation may have, especially when there are a large number of segments, and a high voltage requiring the insulation to be thick. In designing a commutator, it may be observed that

$$r = R - \frac{n \times d}{2\pi}$$

where r is the inside radius of the commutator when put together without the mica, R the inside radius of the complete commutator, n the number of sections, and d the thickness of the mica or other insulation.

The principle of the gauge under discussion is illustrated in the diagram Fig. 5. The hatched portion represents the section of a commutator segment. In trigonometrical language, the line $b\,c$ represents the "cotangent" of the angle $c\,a\,y$, otherwise denoted by the letter θ, which is the angle of the strip.

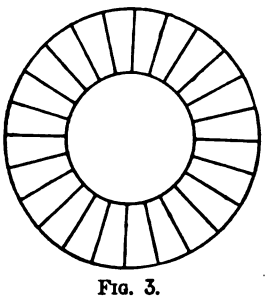


Fig. 3.

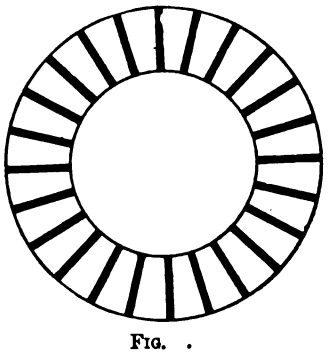

Fig. .

The radius $a\,b$ is unity. It will thus be observed that the taper of the section may be expressed in terms of the gradient of the line $a\,c$, as compared with the horizontal line $x\,y$, obviously to be determined by the number of times $a\,b$ will "go into" $b\,c$. Assuming a 40-part commutator, when θ will be 9°, and making use of a table of natural sines, we find the numerical value of the cotangent $b\,c$ for the angle $\theta = 9°$, to be 6·3138. The line $a\,b$ being unity, the gradient of $a\,c$ will thus be 1 in 6·3138, which may be given as the taper of the segment.

It so happens, that for any number of segments in a commutator, from about 40 up to 160 or 180, if the number of segments be divided by the corresponding numerical cotangent of the angle of one of them, a constant, 6·3, is arrived at when not exceeding one place in the decimals. This is, therefore, useful, since by simply dividing the number of segments by this constant, we arrive at the taper in terms of a gradient.

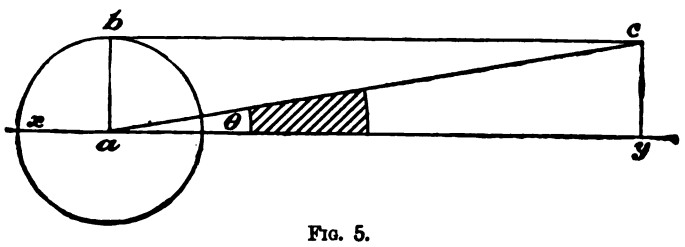

Fig. 5.

Referring again to Fig. 5, it will be observed that the triangles $a\,b\,c$ and $a\,c\,y$ are similar; and $c\,y = a\,b$, and $a\,y = b\,c$. It is also obvious that if we shorten the parallelogram $a\,b\,c\,y$ by moving $c\,y$ nearer to $a\,b$, we shall open the angle θ; and *vice versâ*. Conversely, if the angle be opened $b\,c$ will become shorter, and if θ be closed $b\,c$ will lengthen. Thus for a large number of segments, and consequently a small angle θ, $b\,c$ and $a\,y$ will be much longer than with a small number of segments and consequent large angle. Now $a\,b$ being unity, so also is $c\,y$. The distance of $c\,y$ from $a\,b$, that is, the length of the cotangent $b\,c$, may be calculated for every feasible number of segments in a commutator in the manner stated above, that is, by dividing the number of segments in each case by the constant 6·3. This being done, the various points where $c\,y$ will stand on $a\,y$, in accordance with the number of segments and consequent size of angle θ, may be marked on $a\,y$, and the corresponding number of segments figured on also. A scale will thus be formed on $a\,y$. Subsequently, in order to fix $a\,c$ at the proper slope for any number of segments, it will be merely necessary to make $c\,y$ stand perpendicularly on the mark on the scale having that number.

It is in this manner that the scale on the gauge under discussion is formed, with a standard unit (corresponding to $c\,y$, Fig. 5), of one inch. Hence, to use the tool, a flat standard inch gauge, held perpendicular to the edge of the scale, is placed between the jaws exactly at the mark denoting the number of segments. This sets the gauge open at the required angle or taper. In giving instructions, the distance of the inner edge of the segment from the centre (a, Fig. 5), may also be given; though this must be the small radius with the insulation absent, as shown and explained in connection with Fig. 3. Thus the taper and thickness of the segment are both stated. The gauge, after having been set, is fixed by the fly-nut and cross arm, as shown in the illustration.

THE MAGNETIC CURVE TRACER.

BY PROF. EWING, F.R.S.

The Magnetic Curve Tracer, which was briefly described in *The Electrician* when it was first shown at the Edinburgh meeting of the British Association last August, has now taken a shape which is intended to fit it for use in the workshop as well as in the laboratory, as an instrument for investigating the magnetic qualities of iron. It .ets magnetic quality by exhibiting the curve which connects the magnetisation B with the magnetising force H in any magnetising process. Nothing less than a determination of this curve and of the area which it encloses when the magnetising force is carried through cyclic processes of reversal will suffice to show the comparative suitability of different samples of iron for such electrical uses as the construction of transformer cores. Experiments show that marked differences of magnetic quality are found among specimens of iron wire or sheet which might fairly be rated as soft, and even the knowledge that a particular specimen has high permeability is no guarantee that the loss of energy due to hysteresis, when it is carried through a process of reversal, may not be relatively great. It may be hoped that an instrument which allows comparative tests to be made readily, and at the same time with great completeness, will be of some service to those whose business it is to select their material from batches of nominally "soft," but far from uniform, metal. Tests made by the curve tracer should also be useful in cases where the manufacturer is in quest of the opposite quality, namely, that magnetic hardness or high coercive force which renders certain steels pecu' liarly fit for the construction of permanent magnets.

The curve is exhibited, as readers of *The Electrician* may re member, by the movement of a spot of light reflected on a screen by a mirror, which receives two component motions, one (vertical) proportional to B, and the other (horizontal) proportional to H. Fig. 1 shows the instrument in the form in which it is now made by Messrs. Nalder Brothers. The diagram (Fig. 2) is reproduced to show the function of the various parts. The mirror is pivoted on a single needle-point, which leaves it free to turn both ways, and is connected by threads to the middle of two wires, A A and B B, in such a manner that when either of the wires sags the mirror suffers a corresponding deflection. The threads are kept taut by light springs, the tension of which is adjustable. The wires are stretched in narrow slots, forming gaps in two magnetic circuits, D D and C. One of these circuits, D D, is made up of the iron or steel to be examined, along with suitable pole-pieces and yoke, and the current which passes through the magnetising coils of this circuit passes also through the stretched wire, B B, in the gap of the other magnet. The other magnet is constantly magnetised by a steady current, and a steady current also flows through the stretched wire A A. Hence, when the magnetising current of D D is altered the wire B B sags out or in, and gives horizontal motions to the mirror which are proportional to the magnetising force acting on D D. And when the magnetism of D D is altered, the wire A A sags up or down, giving vertical motions to the mirror which are proportional to the changes of magnetism.

Digitized by Google

The samples to be tested form the arms of D D. They may be solid rods, or rods built up of thin strips or of wire. The rods supplied with the instrument are of soft sheet-iron, built up of insulated strips, with a net cross-section about 1in. by ½in., and about 18in. long. In preparing other rods for comparison of magnetic quality, the same dimensions are to be chosen as those of the standard rods. Clamps are provided at the pole-pieces to allow the rods to be readily inserted and removed.

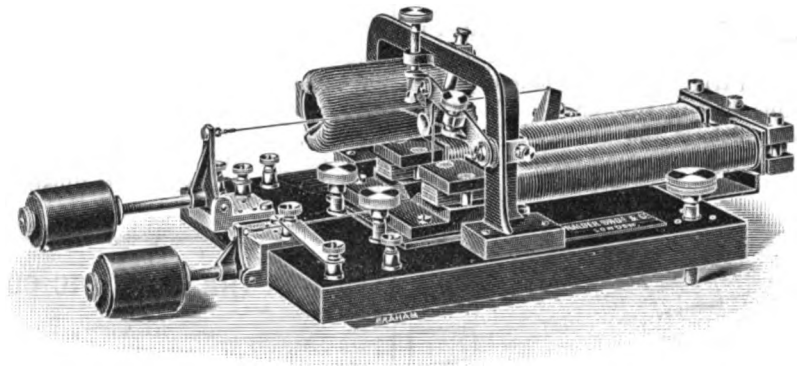

Fig. 1.

The same constant current will serve for the wire A A, and for the magnetising coil of the tubular magnet C. A current of about four amperes will serve well, but more or less may be used, according to the amount of movement which it is desired to give to the mirror. The amplitude of the movements can also be regulated by shifting in or out the weights on the bell-crank levers which keep the stretched wires tight. For high-speed work the wires should be kept very tight, and a small mirror should be used. The magnetising current must be made to vary in a continuous manner; not by sudden makes and breaks. When these precautions are taken, magnetic cycles may be performed so rapidly that the reflected light appears on the screen as a continuous curve. A special commutator is supplied to allow of rapid but gradual variations and reversal of the magnetising current. It consists, essentially, of two fixed and two revolving plates of zinc, immersed in a solution of zinc sulphate.

In ordinary testing, it is more convenient to make the magnetic changes occur slowly, and to mark with a pencil the successive positions of the spot on the screen. A sheet of paper on a small drawing-board, set up against a wall or other vertical support, is a suitable screen, The source of light may be an ordinary galvanometer lamp, furnished with a pair of cross wires instead of the usual single wire. For high-speed work, a small spot of light is necessary, which is obtained by placing a screen with a small hole in it just in front of the lamp. Horizontal and vertical datum lines are marked by moving (by hand) the wires B B and A A respectively, and marking the path of the spot. A variable resistance is to be inserted in the magnetising circuit of D D, to allow successive points of the magnetising curve to be obtained; two zinc plates suspended near together in a weak solution of zinc-sulphate, in such a way that they can be more or less deeply immersed, will serve well for this purpose. A rapid commutator is also to be put in this circuit, to allow the specimens under test to be demagnetised by rapid reversals of continuously-diminishing magnetising force, if it is wished to determine the curve of *initial* magnetisation. In comparing other samples with the standard bars, care must be taken to preserve the same scale of **B** and of **H**, by not changing the constant current in the wire A A and magnet C, nor the tension of the stretched wires.

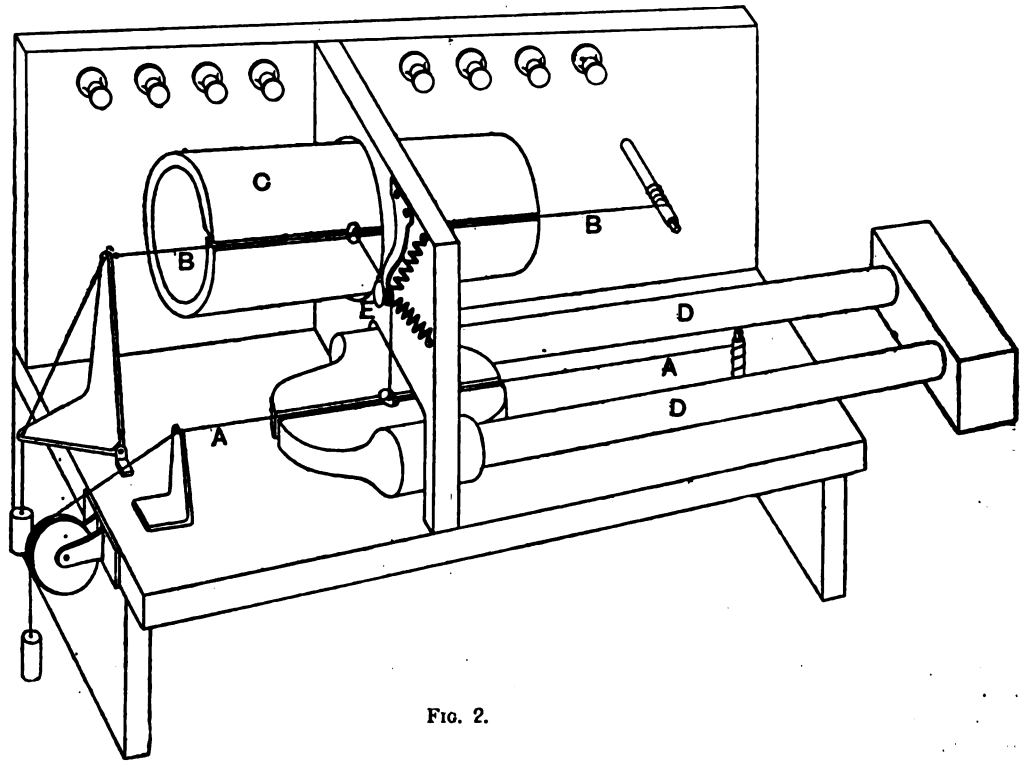

Fig. 2.

The absolute scale of **H** may be calculated, if required, from a knowledge of the number of turns in the winding of the magnet limbs, and that of **B** may be found by means of an auxiliary ballastic galvanometer, by winding an induction coil of a few turns round one or both of the limbs.

Digitized by Google

Fig. 3 shows the electrical connections with the terminals as they are placed on the slate base of the instrument.

Terminals 1 and 2 are those of the coil which magnetise the tubular magnet C; terminals 5 and 6 are those of the main magnet coils on D D. The constant current is supplied by P, and, taking the course 1, 2, 3, 4, passes in series through the magnetising coil of C and the stretched wire A. The variable current is supplied by Q, through the commutator K and adjustable resistance R. Taking the course 5, 6, 7, 8, it passes through the main magnetising coil and the stretched wire B. The copper strip which is used to connect 2 with 3 may be put

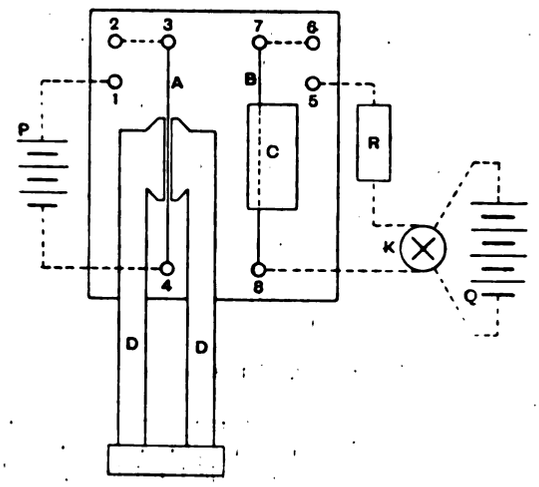

Fig. 3.

between 1 and 3 instead, 2 and 4 being then the battery terminals in that circuit. The effect of this is to change the general slope of the figure on the screen from right to left, or *vice versâ*. One of the two arrangements is right when an ordinary screen is used; the other is right when the screen is a piece of tracing paper or ground glass, viewed from behind.

Care should be taken to adjust the instrument, so that when a complete cycle of magnetic reversal is performed the figure on the screen will be symmetrical, with the extremities equi-

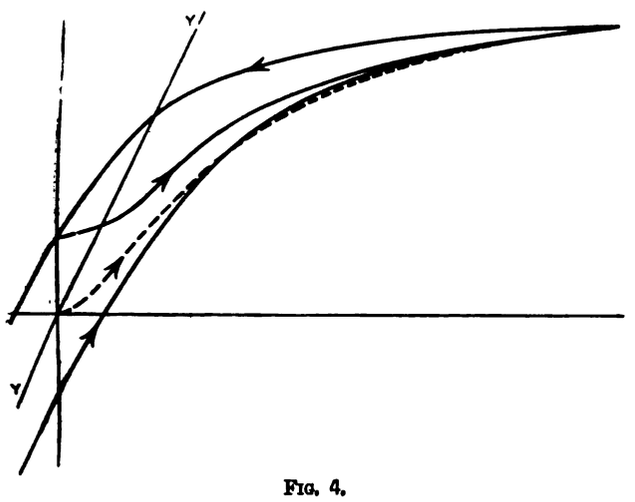

Fig. 4.

distant from the zero point or origin which corresponds to the condition of no current in B and no magnetism in D D. To secure this, see that the stretched wires are, as nearly as may be judged, in the middle of their respective slots, both vertically and horizontally. Set the mean position of the mirror perpendicular to the pivot needle, by adjusting the needle's position by the screws provided for that purpose. The light springs which keep the connecting threads taut are to be set so that they remain considerably stretched even when the mirror moves to its furthest limit in the direction tending to slacken them.

Fig. 4 is an example of the curves obtained by the instrument shown in Fig. 1. It is a copy of one half of a cyclic curve of reversal, along with the initial curve taken after demagnetising the specimen by reversals, and also the curve obtained by reapplying the magnetising current after it had been reduced from its maximum to zero. Owing to the existence of an air gap in the magnetic circuit under test, the diagram is sheared over to the right, and true values of the magnetic force would be found by measuring horizontal distances from some such line as Y Y, instead of from the vertical

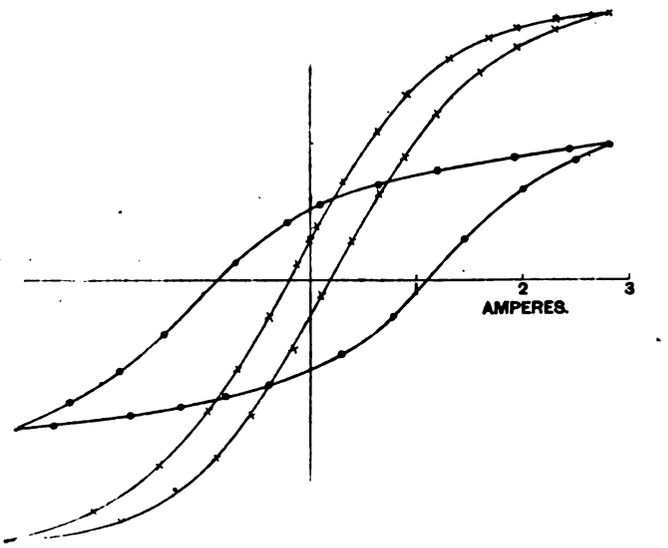

Fig. 5.—Cyclic Curves for Iron and Steel, taken by the Magnetic Curve Tracer.

line. This shearing does not affect the *area* enclosed by the cyclic curves of reversal, and need not, therefore, be taken account of in measuring the comparative amounts of energy dissipated by magnetic reversals in different specimens, or in the same specimens with different values of the magnetism.

Figs. 5 and 6 give further examples of the work the curve-tracer does: they are also tests taken with the instrument of Fig. 1. In Fig. 5 the higher and narrower curve gives the effect of carrying the standard soft-iron bars through a magnetic cycle by reversing a current of three amperes in the magnetising coil. The flatter and wider cycle on the same diagram was obtained (with the same strength of magnetising current) after a pair of steel bars had been substituted for the standard soft-iron bars.

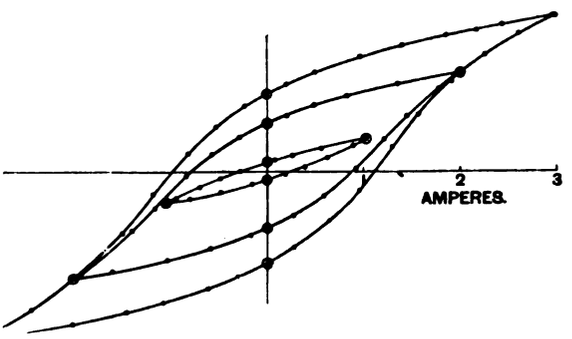

Fig. 6.—Cyclic Curves for Steel, with various Grades of Magnetising Force, taken by the Magnetic Curve Tracer.

Fig. 6, again, shows three cycles obtained with a pair of steel bars, the limits of the magnetising current being three amperes, two amperes, and one ampere respectively. Curves of this type show how readily the instrument may be employed to determine (from the enclosed areas) the relative amounts of heating due to magnetic reversal under different grades of magnetising force, or with different values of the limiting magnetisation.

In these instances the cycle was gone through quite slowly, a pause being made at each of the marked points. When the cycle is gone through comparatively fast, the presence of time lag becomes very manifest, especially when the bars are solid and when the material is soft iron. It is obvious from the behaviour of the spot of light in such experiments that the

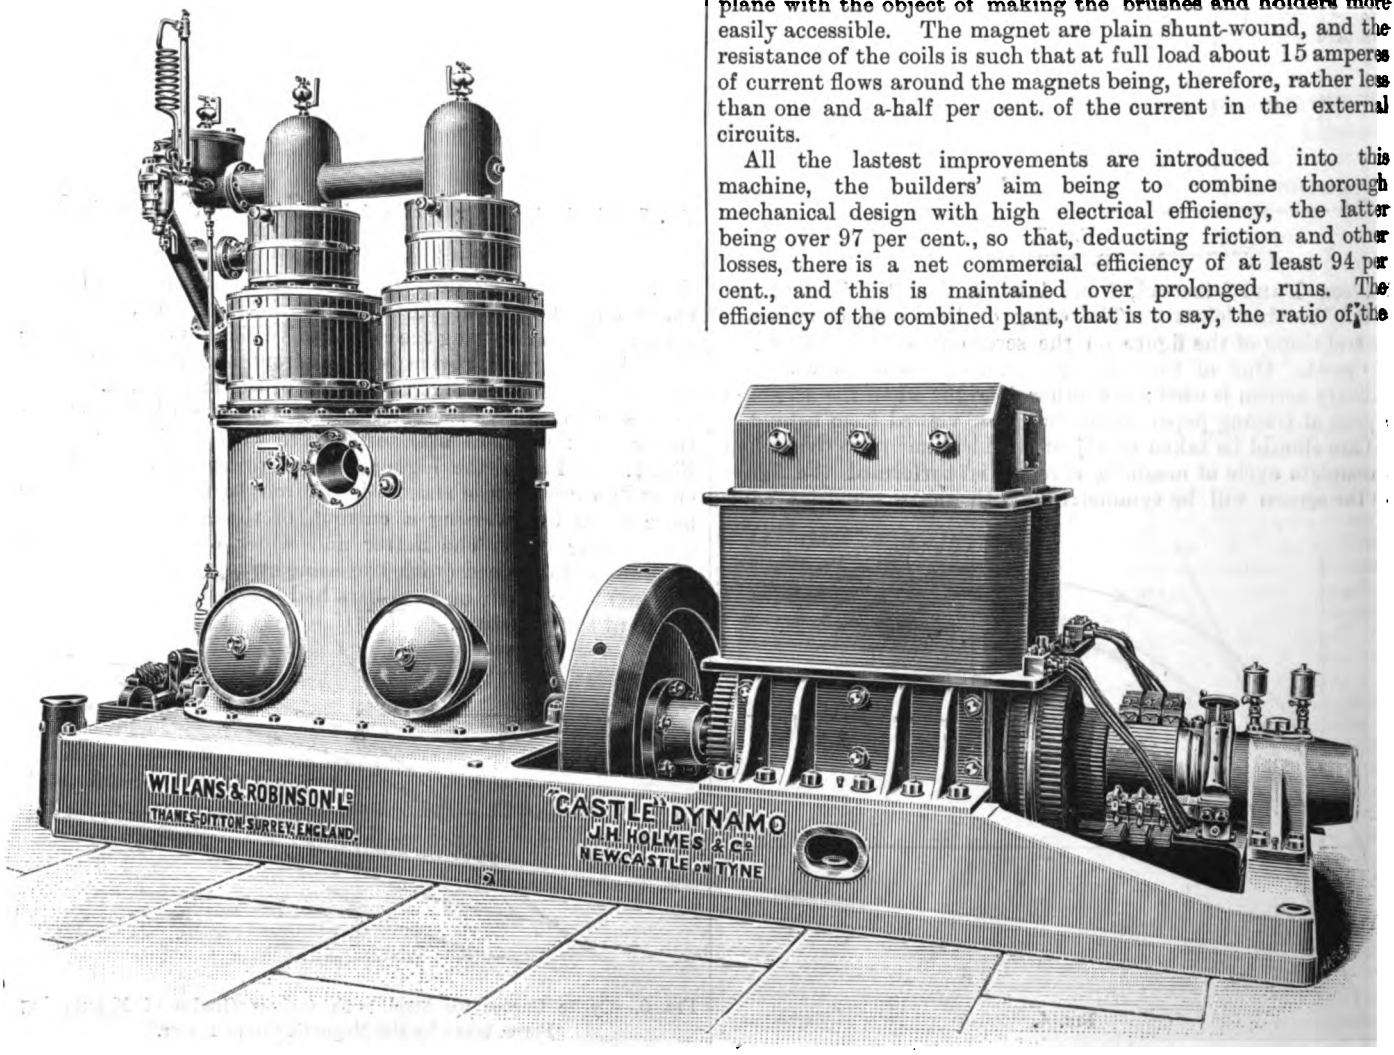
Digitized by Google

time lag is due to no peculiarity of the instrument, but is a genuine feature of the magnetising process.

In addition to its use for determining areas such as those of Figs. 5 and 6, for comparing the magnetic qualities of different samples of iron, and for investigating the properties of magnetic curves generally, the instrument may be used as a galvanometer by making the current to be measured pass through either of the stretched wires, while the magnet, in the slot of which the wire is stretched, is kept in a constant state of magnetisation. This will be found useful in cases where an extremely dead-beat indication is wanted, and by making the spot of light register its position photographically on a moving plate or paper satisfactory records of rapidly fluctuating currents may be obtained.

A LARGE "CASTLE" DYNAMO.

The "Castle" dynamo here described is of Messrs. J. H. Holmes and Co.'s latest improved drum armature type, wound with bar conductors, and is designed for aluminium smelting.



It has an output of 125 volts and 1,025 amperes at a speed of 350 revolutions per minute; thus being capable of supplying current to more than 4,000 lamps of 8 c.p. each. The armature alone weighs considerably over two tons, and has a core built up of about 1,700 thin Swedish charcoal iron discs, carefully insulated from each other by specially-made parchment paper of unusual thinness. The discs are mounted directly upon a steel shaft, and are driven by a key running the entire length of the core, and they are notched in such a manner as to leave three ventilating spaces next to the spindle. The bar conductors are built up of copper strips, so split up and twisted as to prevent, as much as possible, the formation of "eddy" currents, and they are driven in a positive manner from the core by means of drivers which rest in channels at intervals round the periphery; the end crossings or connections are made of copper strips of ample cross-section and without joints, arranged in a compact form at each end of the armature, without, however, interfering with the efficient ventilation of the core to the channels described above. Great care has been exercised in the design of this machine, both by keeping the current density in the conductors small and by eliminating eddy currents, to ensure the temperature of the machine after lengthened runs being as low as possible. The over-all dimensions are 13ft. × 5ft.

The field-magnets are of best annealed iron forgings, machined all over, and weigh, with their copper-windings, about eight tons. These forgings rest upon a brass bed lying on a concrete foundation, and are steadied at the sides by non-magnetic brackets, fastened to the Willans' Patent Combination Frame forming the base of the engine and carrying the outer bearing of the armature. The brush-holders are of massive proportion suited to the large currents they have to convey, and the connections between the armature and the commutator are so arranged as to bring the line of commutation in to the horizontal plane with the object of making the brushes and holders more easily accessible. The magnet are plain shunt-wound, and the resistance of the coils is such that at full load about 15 amperes of current flows around the magnets being, therefore, rather less than one and a-half per cent. of the current in the external circuits.

All the lastest improvements are introduced into this machine, the builders' aim being to combine thorough mechanical design with high electrical efficiency, the latter being over 97 per cent., so that, deducting friction and other losses, there is a net commercial efficiency of at least 94 per cent., and this is maintained over prolonged runs. The efficiency of the combined plant, that is to say, the ratio of the electrical horse-power in the external circuit to the indicated horse-power in the cylinders of the engine at full load, was actually found to be over 86 per cent. during tests recently made at the works of the engine makers. After the engine has been run for a few months, there is little doubt but that the efficiency will reach as high as 87 per cent. or over.

The following are the results of tests of this dynamo, made at Thames Ditton on May 12, 1893, by Mr. F. V. Andersen. Another test was made on the 19th inst., when a number of visitors were invited to visit the Thames Ditton works:—

Dynamo—No. 673 "Castle" dynamo, size 22 G.R., made by Messrs. J. H. Holmes and Co., Portland-road, Newcastle-on-Tyne.

Digitized by Google

Engine—No. 1,430 Willans patent central valve engine, size I.I. compound, made by Messrs. Willans and Robinson (Limited), Thames Ditton.

Duration of Test—Six hours.

Results of Indicating—Mean pressure :—

High-pressure cylinder actual = 32·76,	reduced for	I.P. area =	15·96
Receiver " = 8·68,	"	" =	3·89
Low-pressure cylinder			25·52
Total			45·37

Mean speed 335·7 revolutions per minute.
Low-pressure piston area = 290·4 square inches.
Stroke, 9 inches. Two lines of cylinders.

$$\text{Indicated horse-power} = \frac{335{\cdot}7 \times 290{\cdot}4 \times 1{\cdot}5 \times 45{\cdot}37}{33{,}000} = 201{\cdot}07.$$

Volts at terminals of dynamos, 128·3.
Amperes in the external circuit, 1,006.

$$\text{Electrical horse-power} = \frac{128{\cdot}3 \times 1{,}006}{746} = 173{\cdot}0.$$

$$\text{Combined efficiency} = \frac{\text{E.H.P.}}{\text{I.H.P.}} = \frac{173}{201{\cdot}07} = 86{\cdot}04 \text{ per cent.}$$

Results of Weighing Steam—
1,400lbs. of steam were condensed in 22min. 25sec., which is equivalent to 3,747lbs. per hour.

$$\text{Steam used per electrical horse-power per hour} = \frac{3{,}747}{173} = 21{\cdot}66\text{lb.}$$

Results of Temperature Tests—

Temperature of armature at start	= 29·5°C.
Do. after 6 hours' run at full load	= 57 C.
	Rise = 27·5.
Temperature of room at start	= 23·3°C.
Do. do. finish	= 26·0°C.
Difference	= 2·7

Therefore, the actual rise in armature due to running of the machine was 27·6—2·7 = 24·8°C. = 44·7°F.

THE CONTINUOUS CONTROL OF ELECTRIC LIGHT CABLE SYSTEMS.*

BY DR. M. KALLMANN.

The enormous sums spent in the cables of electric lighting stations during the past few years has made the problems of how best to preserve them from injury, and, when injured, to find the fault expeditiously, two of the most important questions of the day ; and the best means of grappling with such a problem is to be quite clear on the subject of all possible causes of disturbance or injury. To examine all possible means of preserving cables is not the object of this Paper, which is directed to the questions (i.) of continuous insulation tests ; (ii.) of automatic location of faults.

Dr. Frölich, in a valuable Paper† read in December, gave a whole series of methods for the first of these purposes ; but the author considers that they entail the expenditure of much time and material, and in admitting that his methods are useless if the middle wire be earthed at any point, Dr. Frölich has shown the inapplicability of his plan to nearly all central station networks, as in nearly all cases the insulation of one pole is more or less negligible. To make the control effective, it is necessary to have an arrangement which stands or shows an alarm signal whenever the insulation falls below a certain given amount, and the best method of doing this is by means of signalling voltmeters, placed between the pole and earth. The Weston voltmeter is very useful for the purpose, but while this arrangement is satisfactory for small work, it loses its value, to a great extent, on very large cable systems. The author has devised a system of signalling at the station the insulation condition of the smallest possible portion of a large network, but before going into the theory of it he gives an account of some practical arrangements of a Berlin central station, which have been working during many months.

In such a large cable system as that of Berlin injuries are constantly happening to the cable, through workmen and others, and the device is intended to give an alarm at the station whenever such an accident occurs, and to show the district within which it has taken place. In order to do this, the insulated pilot wires, which are also used for voltmeter wires to show the pressure at different points in the system, are made use of. The arrangement is shown (on a two-wire system for simplicity's sake) in Figs. 1, 2, 3. The author then enters into details of the Berlin system, which has about 400 miles of street conductors divided into 115 districts, the area supplied being about 2·5 square miles, and containing about 650 junction boxes, whereby taking out fuses every conductor can be cut off. In Berlin each pair of pilot wires serves an area of about 70,000 square yards, and a cable length of about 1½ mile ; and it is, therefore, generally not necessary to open more than three boxes in order to find the defective cable and cut it out. The arrangement of the combination apparatus is shown in Fig. 1, the essential point being that the pilot wire in each cable is connected to the opposite main, so as to keep up a difference of potential between it and the cable in whose sheathing it is run, in Berlin amounting to 220 volts. At the station each feeder pilot wire has

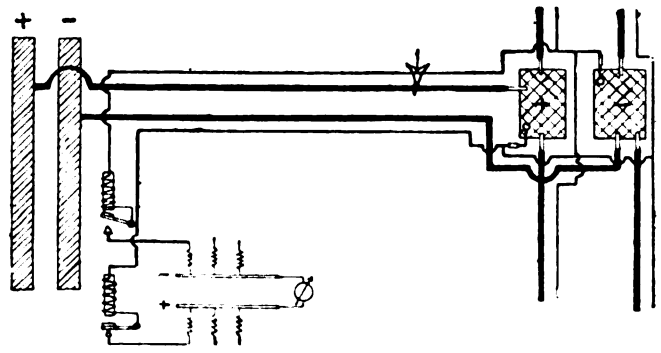


Fig. 1.

a relay in its circuit of suitable sensibility, for the purpose of attracting an armature and ringing a bell if any disturbance of the potential difference between pilot wire and main takes place. By this means any breakdown in insulation is automatically signalled at the station, without disturbing the measurements of pressure which are carried on through the same wire ; and the relay which has been set in action drops a number, which indicates the district in which the breakdown has taken place, where the defective section can easily be detected and cut out. The author states that practice shows that, even if the cable is only severely injured, without actually short-circuiting the pilot wire to the cable, the earth-current quickly destroys the insulation and brings the two into contact within a short space of time.

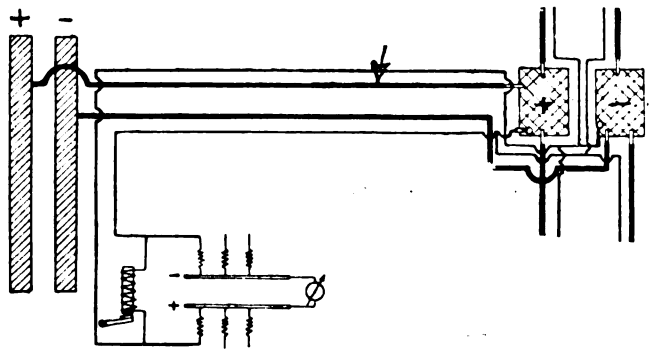

Fig. 2.

The arrangement of Fig. 2 enables one relay to be used for both pilot wires belonging to the same district. It is found that the sensibility can be so arranged that any defect of insulation, even short of a short circuit, is immediately signalled. Fig. 3 shows an arrangement by which the difference of potential between the pilot wire and main can be lessened if necessary, but no difficulties have arisen in Berlin from this source.

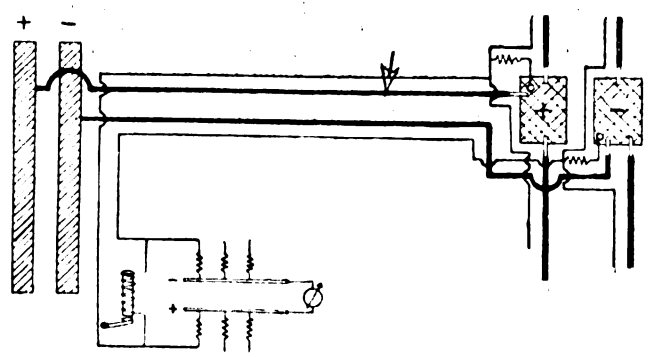

Fig. 3.

In addition to this signalling apparatus, there is provided for the Berliner Elektricitäts-Werke a system of automatic earth-contact signalling arrangements, which can be applied to any system of cables of whatever kind, and of whatever size it may be. The

* Abstract of a Paper read before the Electrotechnischer Verein.
† See *The Electrician*, Vol. XXX., February 10, 17, 24, 1893.

Digitized by Google

theory of this arrangement rests on the fact that, when an "earth" takes place, most of the energy is converted into heat in the immediate neighbourhood of the "earth," and there is only a small fall of potential through the earth itself. The idea is to determine the potential at various points in the earth when the contact takes place; the position of the fault is then shown by a relay and a 10-volt voltmeter at the station.

Fig. 4, which is self-explanatory, shows the arrangements for two districts. From the points in the network most removed from one another—for example, from every feeder junction box—an insulated wire P leads to the station, and passing through a relay R, is put to earth. From the other pole, or middle wire, a conductor which can be cut out leads to earth at the station, if necessary through a resistance. Each pilot wire P is also put to earth in its own district, and the relay has, therefore, on its terminals the difference of potential between the earth at the station and at the district corresponding to it. This difference is small, even if several hundred amperes are passing to earth, as the fall of potential is so very local; and the disturbance can be measured on a low-tension voltmeter quite easily. This controlling device can be made of any desired degree of sensibility by suitably winding the relays; and, as in Berlin it is not desirable to have it too sensitive for fear of needless alarms and so on, the relays are wound accordingly (1·8 volts for the Schiffbauerdamm district, for example). If the short circuit is very severe, many of the nearer relays may also give a signal, as the required difference of potential may be reached nearer the station. To find the position of the fault in this case, a voltmeter, G, is used, consisting of a simple telegraphic galvanoscope. This can be put between the "earth"

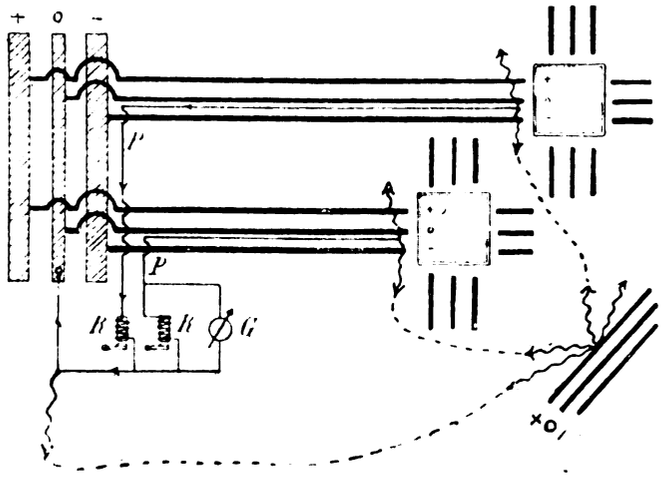

Fig. 4.

at the station and those of the various districts, by means of a switch passing over a series of blocks connected to the control wires. The galvanoscope works either with 0·5 or 5 volts at its terminals for maximum reading. The contact at which the highest potential difference occurs is that of the district in which the "earth" is to be found.

The remainder of the author's Paper is taken up with the theoretical aspect of this arrangement and a description of his experiments. He concludes by calling attention to the two interdependent systems by which a complete and continual control over the whole cable network is attained, the first directed chiefly to direct injury of the street cables, while the second in general watches over all faults of insulation, signalling when they pass a certain limit, and applicable not only to underground covered cables, but also to bare conductors in culverts and to overhead wires; while it controls, in addition, all the house installations, thus making the control most complete and effective.

ON THE REACTION OF THE ARMATURE CURRENT ON THE FIELD.*

BY J. FISCHER-HINNEN.

The method of Hopkinson for the predetermination of the magnetising force required in dynamos is found to be only correct in certain cases when, through weakness of the armature field, its reaction on the magnets may be neglected. Many attempts have been made to get some quantitive predetermination of these reactions, but no universally applicable methods have yet been published; most of these attempts have been fully described in the technical papers. The following methods are more or less novel, and although they have no pretence to mathematical accuracy, they will be found to lead to results which will prove of practical utility.

A.—Two-pole Machines.

Fig. 1 represents one of the usual types of machine in section. It will be noted that the current is flowing in one direction in all wires above the neutral line $n\,s$, and similarly in the reverse direction in those below this line. The armature naturally becomes a magnet, the magnetic axis of which lies along $n\,s$. But since the large iron masses of the pole-pieces lie close to this armature, the magnetic lines leak out into this iron in seeking to shorten themselves as much as possible; one can assume without sensible error that they are approximately evenly distributed over the entire surface of the armature.

Calculation of the Armature Lines of Force.

If Z_a represent the total lines in the armature produced by the armature current, it is clear that Z_a may be calculated from the formula

$$Z_a = \frac{0{\cdot}4\,\pi\,A\,T}{R_1+R_2+R_3}. \quad \ldots\ldots\ldots \quad (1)$$

Where A T (for drum armatures) is the number of ampere turns on the armature, and is equal to the total number of wires (n) multiplied by the current in them and divided by the number of poles ($2\,p$). For Gramme armatures this figure must be multipled by

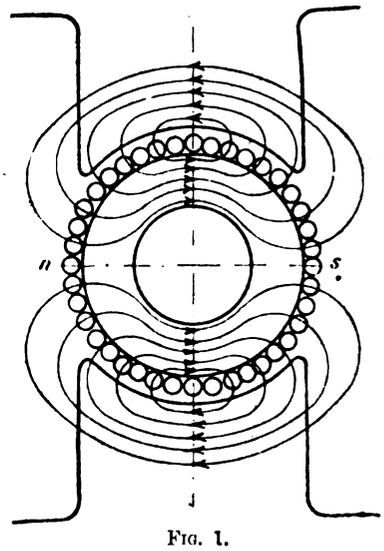

Fig. 1.

about 1·5. R_1 is the magnetic resistance in the iron of the pole-piece, R_2 is the magnetic resistance in the iron of the armature, R_3 is the magnetic resistance in the air-gap.

Two cases must now be considered, namely:—(i.) Suppose the armature lines to have a direction at right angles to those of the field-magnet, then it is clear that R_1 may be neglected. This case is the usual one, if the machines have not pole-pieces with long "horns." (ii.) If the horns of the pole-pieces are long and pointed, then in these pieces the field lines and those from the armature are in one in the same, and in the other in the opposite direction. The field is thus weakened in one and strengthened in the other. But even in this case the resistance R_1 is small compared with R_2 (the air resistance). The same is true in even greater degree of R_2; so that in reckoning Z_a we have chiefly to deal with R_3, which can be determined as follows:—

First estimate the average length of path of the armature lines, which will be distributed approximately as in Fig. 2, from which we have as the total length of air path,

$$L'_3 = \frac{2}{d\,e}\left(a\,b \times \delta + \frac{b\,e \times b\,e \times \pi}{2}\right)$$

δ = length of air gap.

If the polar surfaces are differently placed with regard to the armature, allowances must be made; but the sketch fits most modern machines.* For the area of the air path, Q'_3, take the total armature area divided by the number of poles. In toothed armatures, to allow for crowding at the teeth, a somewhat smaller area must be taken, but this is not now a common type of armature.

* Abstract from the *Elektrotechnische Zeitschrift*, February 3, 1893.

* Do not confuse L'_3 the length of the lines due to the armature in air, with $L_3 = 2\delta$, the corresponding magnitude due to the magnet. It will be noted that the value of L'_3 depends much more on the arc embraced by the poles than on the air gap.

Digitized by Google

For example, let us suppose Fig. 3 to represent a certain achine, and let $b=16$cm., $a=8$cm, $\delta=1$cm, $c=7{\cdot}5$cm., the length armature being 30cm. From this we get :—

$$L'_3=2/24\ (16\times1+8\times7{\cdot}5)=6{\cdot}3\text{cm.}$$
$$Q'_3=2\ (16+8)\ 30 \qquad =1440\text{ sq. cm.}$$

Calculation of the Displacement of the Brushes.

Z_a = number of lines due to armature.
Z = ,, ,, due to field (per pole).

Set off graphically these values in their proper directions, and nstruct, as shown in Fig. 4, a parallelogram of forces. The sultant gives the approximate direction of the new magnetic is, so that

$$\tan a=Z_a/Z \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

here a is the angle of displacement of the brushes.

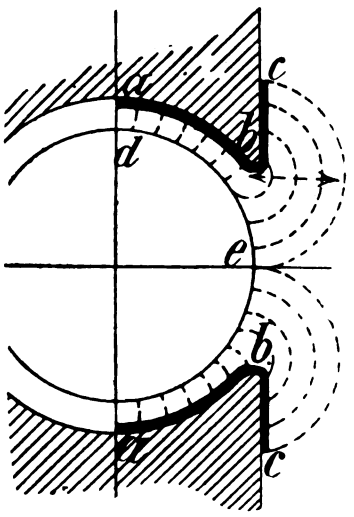

Fig. 2.

This formula is certainly theoretically open to objection, since it ppears at first sight more probable that the resultant axis would rm a right angle with Z_a, so that the sine would have to be sub-ituted for the tangent ; this is, however, obviously an erroneous ew, for it would not allow Z_a to become greater than Z, and perimental results show this to be possible. The author finds that e tangent law holds good generally, but tends to make the angle a ade small.

Let us take, as an example, the data of a two-pole machine with cinotti armature :—Diameter of armature = 62·2 cm., length of mature = 40·0, strength of current (J) = 500·0, number of wires) = 140, number of commutator sections = 70, width of teeth 0·55 cm., width of interval = 1·4 cm., $b=35$ cm., $a=14$ cm.,

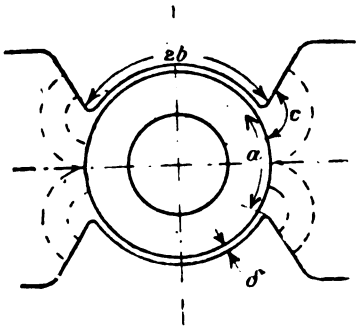

Fig. 3.

19 cm., $\delta=0{\cdot}6$ cm., Z (total field lines) = 10,800,000, armature pere turns = 17,500.

$$L'_3=11{\cdot}7\text{ cm.}, \qquad Q'_3=2{,}730\text{ sq. cm.}$$
$$Z_a=\frac{\cdot4\ \pi\times17{,}500}{\frac{11{\cdot}7}{2730}}=5{\cdot}15\times10^6,$$
$$\tan a=\frac{5{\cdot}15\times10^6}{10{\cdot}8\times10^6}=0{\cdot}477$$
$$a=25{\cdot}5°.$$

With this machine it was found that sparking was excessive ; position of least sparking was determined and found to be out 27°. It was then bored out, so that the air gap was reased to 1cm., and the pole horns reduced ; then the new dimensions of the poles were :—$b=30$cm., $a=19$cm., $c=22{\cdot}4$cm., $L'_3=18{\cdot}6$cm., $Q'_3=2{,}730$ sq. cm., $Z_a=3{\cdot}23\times10^6$, $\tan_a=0{\cdot}3$, $a=17°$. Experiment showed that the angle at which the brushes ran sparklessly was a shade over 18°.

Calculation of Compensating Winding.

The armature reaction may be considered as of two kinds, a direct and an indirect effect. In Fig. 5 the direction in which

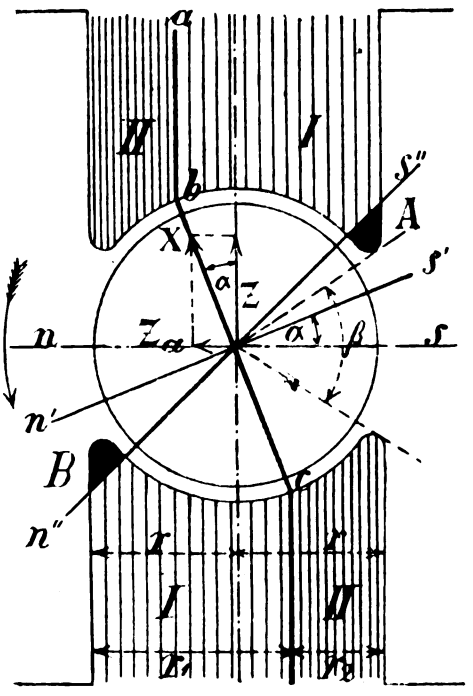

Fig. 4.

the armature lines leave the armature for the poles is shown by arrows. It is here clearly seen that those from $a\ b$ and $c\ d$ tend to reduce the field from the magnets, and to strengthen it along $a\ c$ and $b\ d$. The dominant effect is the weakening one, and amounts to

$$\tfrac{1}{2}Z_a\left(\frac{90+a}{90}-\frac{90-a}{90}\right)=Z_a\frac{a}{90}\text{ lines.}$$

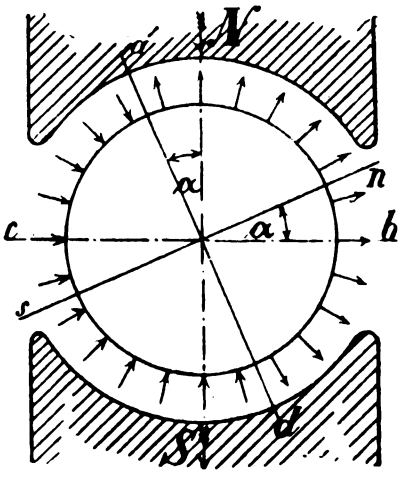

Fig. 5.

This field may be compensated for by providing the magnets with an extra winding, equal in effect to the above disturbance, that is to say, with

$$\frac{10}{4\pi}I'_3\left(\frac{Z_a}{Q'_3}\cdot\frac{a}{90}\right) \quad . \quad . \quad . \quad . \quad (3)$$

ampere turns per magnetic circuit.

The secondary effect is indicated in Fig. 4, and is the crowding of the magnetic lines in the magnets towards one side. Supposing z_1 to be the density before disturbance then approximately

$$\text{in I}: z'_1=z_1\cdot\frac{1}{1+\sin a} \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$
$$\text{in II}: z''_1=z_1\cdot\frac{1}{1-\sin a} \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

Digitized by Google

It is easy to show that the result of all this is to increase the magnetic resistance in the pole-pieces, and to diminish the total number of lines of force. A weakening, however, also results from the fall of volts as the load is increased. This fall can, however, be calculated to some extent, by determining by a few preliminary calculations by well-known methods the difference in the number of lines produced. It is more practically useful to know by how many ampere turns the magnet-winding must be increased to compensate for this secondary action of the armature. The following formulæ of Hopkinson may be applied. Let L_1 represent the length of path of magnetic lines in both pole-pieces, then the number of ampere turns required for this part of the path and for the original density Z_1

$$\frac{10}{4\pi} L_1 f(Z_1) \text{ ampere turns,}$$

where $f(Z_1)$ is taken from the magnetisation curve of the iron in the usual manner.

For the new densities Z'_1 and Z''_1 we have

$$\frac{10}{4\pi}\left[\frac{L_1}{2} f(Z'_1) + \frac{L_1}{2} f(Z''_1)\right] \text{ ampere turns, . . (6)}$$

which gives a difference of

$$\frac{10}{4\pi} L_1 \{\tfrac{1}{2} f(Z_1') + \tfrac{1}{2} f(Z_1'') - f(Z_1)\} \text{ ampere turns . (7).}$$

We have then, following out the former reasoning, as total ampere turns required to compensate for the total armature reaction

$$\frac{10}{4\pi}\left[L_1 \{\tfrac{1}{2} f(Z_1') + \tfrac{1}{2} f(Z'_1) - f(Z_1)\} + L'_3 \frac{Z_a}{Q'_3} \cdot \frac{a}{90}\right]$$

ampere turns . . (8).

Let us take as an example the data of an ironclad machine with smooth-cored armature. D = 15 cm., l = 11 cm., J = 50 A, n = 150, Z = 1,000,000, L_1 = 28, Z_1 = 8,000 (cast iron poles), L'_3 = 2·2, Q'_3 = 260, ampere turns on armature = 1,900. $Z_a = 0{\cdot}28 \times 10^6$, tan α = 0·28, α = 15°40′, sin α = 0·27.

Put these values in equations (4) and (5) and we find Z'_1 = 6,300, Z'_1 = 10,900, $f(Z_1'')$ = about 250, Z_1 = 8,000, $f(Z_1)$ = 68, and finally from (8) we obtain ampere turns = 1,920 as the value of the compensating winding for the magnets, making a total of 6,500 + 1,920 = about 8,500 A T.

The author calls attention to the following interesting conclusions from the above formulæ.

(*a*) If the poles and magnets are working at a fairly low density, and the pole corners fairly close together, while Z_a is small compared with Z and δ, the air gap, relatively large, then approximately

$$Z = 0{\cdot}4\pi \text{ A T (magnets)} \times Q_3/L_3$$

where Q_3 is the area of section of pole $L_3 = 2\delta$, and also

$$Q_3 L_3 = Q'_3/L'_3,$$

and equation (2) becomes

$$\tan \alpha = \frac{\text{A T of armature}}{\text{A T of magnets}}$$

in this case also, the first term of (8) can be neglected and the ampere turns required for compensation (3) become

$$\text{A T} = \text{armature A T} \cdot \alpha/90.$$

(*b*) The compensation winding is only an increase in the magnetising force of the magnets, and its position is of no importance. The arrangement of Thomson-Houston, constructively difficult, whereby the turns are placed directly over the armature, has no advantages.

(*c*) An excessive increase of Z_1'' makes the compensating winding an impossibility, and Z_1 $1/1 - \sin \alpha$ should always be less than about 12,000 for cast or 20,000 for wrought iron. These formulæ may be utilised in designing the machine to control the ampere turns on the armature. Thus, supposing one replaces the sine by the tangent function, taking the value

$$\frac{Z_a}{Z} = \frac{0{\cdot}4\pi \text{ A T (armature)} Q'_3}{L'_3 Z}$$

then

$$\text{A T (arm)} < \frac{10}{4\pi} \frac{L'_3}{Q'_3} Z u \sqrt{\frac{1}{1-u^2}} \quad . \quad . \quad . \quad (9)$$

$$\cdot \quad \cdot \quad u = \frac{z_1 \text{ max.} - z_1}{z_1 \text{ max.}}$$

A further simplifi ation may be obtained by assuming in this special case

$$Z_a/Z = \sin \alpha, \text{ instead of } \tan \alpha,$$

when (9) becomes

$$\text{A T (arm)} < \frac{10}{4\pi} \cdot \frac{L'_3}{Q'_3} \cdot Z \cdot u \quad . \quad . \quad . \quad . \quad (10)$$

This simplification tends to make the value too small, and is, therefore, on the safe side.

For example, in the machine dealt with in the last example the actual ampere turns on the armature were 1,900. The sine formula gives A T (arm) < 2,060, the tangent A T (arm) < 2,130, showing that the machine is just at the point where complete compensation can take place. It must be noted that no great accuracy should be attempted in these calculations, as, naturally, the very complicated armature reactions cannot be accurately dealt with by such simple formulæ.

B.—*Multipolar Machines.*

This section of the Paper deals with multipolar machines in a similar way (*see* Fig. 6), and arrives at the formula

Compensating amp. turns

$$= \frac{10}{4\pi}\left[L_1 \{\tfrac{1}{2} f(z'_1) + \tfrac{1}{2} f(z_1) - f(z_1)\} + L'_3 \frac{Z_a}{Q'_3} \cdot \frac{ap}{90}\right]$$

where p is the number of pairs of poles ; and examples are given.

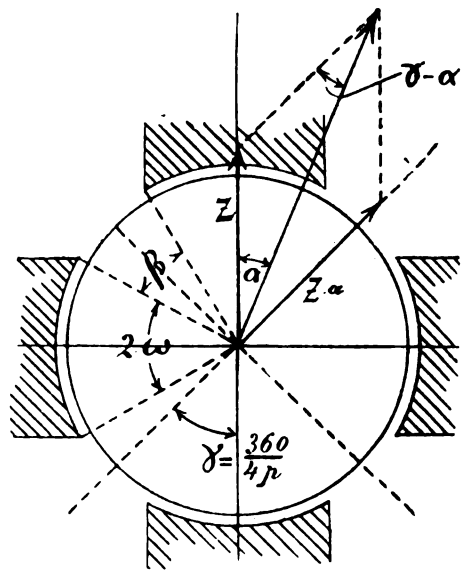

Fig. 6.

C.—Means of diminishing the Armature Reaction.

The knowledge of the amount of armature reaction affords means of designing machines with more satisfactory results ; but it is even more important for the designer to know under any given circumstances how to counteract the effect. Some methods have already been suggested, namely, diminution of armature ampere turns, large air gap and small pole faces. But these methods have the disadvantage that they are directly productive of heavy machine for given output. On the other hand a strong armature reaction means a correspondingly strong magnet winding, and this has

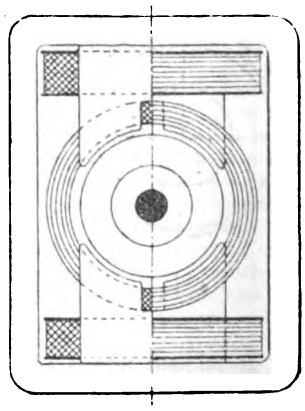

Fig. 7.

can under unfavourable circumstances become larger than the magnet winding proper. It is, however, plainly illogical to try and combat the harmful effect of the armature while the cause of the effect remains untouched. The foregoing considerations, however, point to a method of cure which has none of the above-named disadvantages.

The reactive effects depend on the ratio Z_a/Z. Now, Z_a depends on the magnetic resistance of the path in the air armature and pole-pieces. The latter factor may be considerably increased by lamination of the pole-piece in the plane of the armature axis. This

Digitized by Google

method has also been suggested by Prof. Silvanus Thompson. It presents, however, some constructive difficulty. Tests of this cure were carried out on a Manchester type machine of 1,000 amperes and 10 volts. In its original state this machine gave a brush displacement of 60deg. at full load, and even then there was considerable sparking ; the volts fell from 16 at open circuit to 10 at full load. The same machine then had then the pole-pieces slit in the way indicated above. The result was astonishing. The sparking (up to 800 amperes) became very small indeed. A further displacement of the brushes was not possible as the angle α became greater than β. The displacement was not half as much as before, but the drop was about the same.

In conclusion, the author refers to a second method of diminishing armature reactions, which consists in placing as closely as possible over the armature a winding such that its plane is at right angles to the neutral zone. (*See* Fig. 7.) The magnetising current is in such a direction as to oppose the ampere turns of the armature ; and he points out that this arrangement is better than that of the Thomson-Houston Company, in that it works directly on the armature reaction, and consequently is not so inordinately large. If this winding has as many ampere turns as the armature itself, and distributed equally over the pole surface, then the armature reaction is entirely eliminated. This system may be used even when equation (5) no longer holds. Experiments performed with the Manchester type machine described above showed this

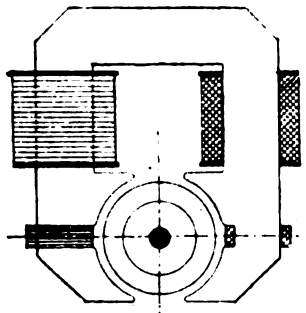

Fig. 8.

clearly ; it was run at a contant speed at 8 volts and 800 amperes, and the brushes had to be very much displaced. The compensating winding had no current in it. As the current in this winding was increased, the sparking became worse, and the brushes had to be put back. When finally the ampere turns on the compensating coil were slightly greater than those on the armature, the brushes were exactly on the neutral zone, and the measuring instruments showed 10 volts and 1,000 amperes—that is to say, nearly 50 per cent. greater output without a sign of a spark being visible.

The author therefore concludes :—"The armature reactions can not only be entirely eliminated in this way, but the output of the machine can also be considerably increased." He also points out that the coil may be arranged in two-pole machines, as in Fig. 8, but he thinks that this arrangement is not quite so effective as the former.

THE PHYSIKALISCH-TECHNISCHE REICHSANSTALT IN 1891-92.

According to a report recently presented to the Reichstag (see *Zeitschrift für Instrumentenkunde*) the work of the Imperial Physico-Technical Institute at Berlin has, during the last two years, gained considerably in extent and importance. Founded in 1887 as a branch of the Normal-Aichungs-Commission, its object has been to construct a series of electrical, optical, acoustical, and other standards, based upon the most precise measurements and the best theoretical principles, for the use of the professions and trades requiring exact physical data. In the last two years over 19,000 thermometers were tested at Berlin, and the testing of as many more supervised at the branch establishment of Ilmenau, in the midst of the Thuringian glass-working districts. Extensive investigations were conducted into the qualities of some new kinds of Jena glass, suitable for thermometers. Instruments were constructed of one of these, capable of directly measuring temperatures up to 550 C., the evaporation of the mercury being prevented by some compressed carbon dioxide contained in a bulb at the top of the stem.

Among other instruments tested, were mercury and aneroid barometers, viscosity meters, petroleum testers and manometers. Water-level indicators for steam-boilers were made of a new kind of glass invented at Jena, the so-called *Verbundglas*, consisting of two layers of different thermal expansions, which greatly reduced the strains due to differences of temperature.

The work in the electrical department consisted chiefly in the construction of standards of resistance and electromotive force, and in the testing of insulating materials. The Clark standard cell was brought to a high degree of perfection, and the effects of varying the proportions and the purity of its constituents were fully determined. A great amount of activity was concentrated upon the task of constructing the Siemens unit of resistance in the best possible manner, and the results were published in papers by Messrs. Holborn, Wien, Kreichgauer, and Jäger. Wire resistances were also constructed, chiefly of manganese-copper, or nickel-manganese-copper alloys, and a series of measurements was made to determine the conductivities of platinum and its alloys.

In the optical department the chief work consisted in the construction and comparison of various standards and sources of light. The Violle-Siemens unit of light, viz., the amount radiated by 1 square centimetre of platinum at its melting point, proved to be very difficult of practical adoption. The use of block platinum was precluded by the difficulty of maintaining it in a state of sufficient purity during melting, and platinum foil was apt to tear at the critical moment. It was, therefore, decided to fix upon some temperature below the melting point, and to determine that temperature by the ratio of the total energy radiated to that transmitted by a layer of water contained in a vessel with plane-parallel quartz sides, a ratio which was found to be constant for a given temperature, and to vary rapidly on heating or cooling. The amount of radiation was measured in each case by means of a very delicate bolometer.

Strong sources of light, such as arc lamps, were compared with constant-current incandescent lamps by reducing the luminosity of the former by an Aubert sector, which can be adjusted to different angles so as to transmit a varying proportion of light through a circular area, the light being then uniformly distributed over the area by rapid rotation. Two illuminated patches were thrown side by side upon a screen, and the rotating sector adjusted till the boundary vanished. In the case of differently-coloured sources, the boundary was adjusted to its *greatest indistinctness*.

A great want seems to have been supplied by the arrangements for testing tuning-forks, upwards of 1,100 of them having been dealt with in the two years. A standard tuning-fork was made of polished steel, avoiding any rough surfaces or markings, which were found to encourage oxidation.

The properties of aluminium were investigated in a variety of ways, the chief object being the production of alloys capable of resisting weather, and suitable for divided circles. This work was carried out at the instance of the military authorities. Aluminium coated with brass rich in zinc was found to give good results.

A great deal of attention was given to the purification of mercury, platinum, and zinc. The former was obtained by electrolysis and distillation in a state of such purity, that the most delicate analysis could not find perceptible traces of impurities in a mass weighing 200gr. Platinum was obtained pure to at least 99·99 per cent. by converting into the double chloride of sodium and platinum. The impurities contained in the purest commercial zinc, consisting chiefly of lead, cadmium, and iron, were reduced from 1 in 3,000 to 1 in 100,000 by a process of combined electrolysis and distillation.

In the course of the last year, negotiations have been conducted and meetings held with a view towards adopting a uniform system of screw threads for the use of watch and clock-makers and other purposes of *feintechnik*. No final decisions have as yet been arrived at, and the movement has lately been deprived of one of its most strenuous and devoted advocates in the person of Dr. Loewenherz. But it is hoped that the demand will soon become an international one, and that it will become possible to execute delicate repairs anywhere, without the necessity of boring a new hole for every screw replaced.

The West-End Street Railway of Boston.—The gross earnings of this Company for the six months October, 1892 to April, 1893, show an increase of 7¼ per cent. over the corresponding six months of 1891-92 ; the net earning increase is no less than 34 per cent. This shows a reduction in the operating expenses from 79½ per cent. of the gross earnings to 74½ per cent., although the cost of removing snow was considerable greater than formerly. This decrease in operating expenses is due to the fact that this year 69 per cent. of the revenue car-miles were run by electric power and 31 per cent. by horses, while last year 38 per cent. were by electricity and 62 per cent. by horses ; and, also because, with motors cased in iron and running in oil, the of repairs needed are far less than with motors of the old kind which were exposed to the snow, water, and dirt.

LEGAL INTELLIGENCE.

National Telephone Company (Limited) v. Harston.

Judge Ellison, in the Sheffield County Court, on Thursday, gave his decision in this matter (which was fully reported in our last issue). In iving judgment, his Honour said plaintiffs claimed £45. 10s. as the rent for telephones connecting defendant's establishments from December 1, 1891, until January 31, 1893. Plaintiff had paid into Court £29. 11s. 4d., the point in dispute being as to whether defendant was entitled to a reduction in terms, which came into force after the agreement. His Honour held that defendant was entitled to such a reduction, and gave judgment for plaintiffs for the amount paid into Court.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *May* 12, 1893.

The Trolley Patents.—The fundamental patents recently issued to C. J. Van Depoele in behalf of the General Electric Company have been made the ground for a suit brought by that Company against several electric railway companies for an infringement of patent rights. It is probable that this is the initiation of an important legal battle which, possibly, may last as long and prove as interesting as that which has been fought for the past five or ten years over the invention of the incandescent electric lamp. It is difficult to believe, however, that the General Electric Company seriously anticipates securing a monopoly of the trolley, and it is, perhaps, rather a bluff on its part to put a better face on its financial condition than to secure any extension of its present control of the electrical business. In the recent financial crisis the stock of the General Electric Company was affected far more than that of any other electrical concern. It should not be thought, however, that this is a fair indication of the present condition of the General Electric Company, for it was undoubtedly due in a large measure to the general condition of the stock market, and to the fact that electrical securities are not yet taken in this country as the most desirable of investments.

Telephone Litigation.—The American Bell Telephone Company has filed a Bill in the United States Circuit Court of Pittsburgh against the McKeesport Telephone Company for infringement of its patent, dated January 30, 1877. The McKeesport Company recently began operations in the belief that the fundamental patents held by the Bell Company expired on January 20th and March 20th of this year. The Bell Company, however, claims that its fundamental patent, which does not expire until January 30, 1894, has been infringed by the McKeesport Company, and has asked the Court for a preliminary injunction. The case will excite widespread interest, as many other telephone companies are preparing to place instruments upon the market as soon as they feel assured that they will not immediately be enjoined by the Bell Company.

CORRESPONDENCE.

COOKING AND HEATING BY ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I can endorse Mr. Dowsing's remarks in his able letter on cooking by electricity, except in one particular. The conclusion at which he arrives, that electrical cooking can be performed at a cheap rate, comparing favourably with the cost of cooking by coal, is doubtless correct, and this fact cannot be made too widely known. This more especially among the electrical trade, as an idea seems to prevail that cooking takes "a frightful lot of current."

I am now making cooking apparatus which will cook a small leg of mutton, or a fowl, with about 5lb. potatoes and cabbage, with an expenditure of current equal to about two-thirds of a unit.

The following test with one of our ovens will show you some data, which, however, I think I can still improve upon:—

Time.	Temperature.	Current.	Pressure.
0	12° C.	9 amperes	100 volts
5 minutes	49° C.	9 „	100 „
10 „	108° C.	9 „	100 „
15 „	180° C.	9 „	100 „
20 „	225° C.	9 „	100 „
(The current reduced after 20 minutes).			
25 minutes	205° C.	3·5 amperes	100 „
30 „	195° C.	3·5 „	100 „

The temperature remains steady at 195°C. with 350 watts for three hours after this.

The exception which I have to make to Mr. Dowsing's figures refers to boiling water. He does not state the initial temperature of the water to be boiled, but simply says, "to boil a quart of water requires about 3½ amperes for ten minutes." This state of efficiency I have not been able to reach, nor can I understand how Mr. Dowsing can attain it, as it is beyond the theoretical efficiency calculated upon Joule's law. This law teaches us that 1 watt acting for 1 second developes ·238 calorie, or, in other words, raises 1 gramme of water 1°C. in 1 second. Taking 1 pint of water to weigh 1¼lb., and the initial temperature of water at 15°C., we can calculate that 1,000-watts will boil such water (or raise the temperature by 85°C.) in 3·383 minutes. I am now selling copper kettles which will perform this operation at an expenditure of current which equals 1,000 watts for 3·8 minutes per pint, and which gives about 90 per cent. of theoretical efficiency. More than this I have not been able to achieve.

As it has not yet been publicly stated, I may mention that my method of manufacturing electrical cooking and heating apparatus (as carried out by my firm, the General Electric Company) differs essentially from the American or Crompton's methods (which I myself first introduced into this country during the Exhibition at Crystal Palace), and I claim that I have thereby gone an important step in advance.

The insulating and refractory material is a cement which can be applied to the surface to be heated without baking or subjecting to heat. I have found that enamel, which is being used in the American method, cracks, and thereby reduces the protection aimed at, viz., that of excluding atmospheric oxydisation. The cement has no deteriorating influence on the resistance wires, allows the use of an extremely thin film of insulating division between such wires and the surface to be heated, and thus renders the apparatus very durable and efficient.

I note that in your Editorial Notes you remark that you hope the price of the apparatus will soon be reduced. I have already taken steps to accomplish this object, and have no doubt that the apparatus will in time be sold at prices within the reach of everybody. I have found great difficulty in getting the right articles made suitable for my method of manufacturing, but this is gradually being overcome, and if the demand is large enough, which I hope it will be, the cost of manufacturing, and consequently the selling price, will be materially reduced.—Yours, &c.,

G. BINSWANGER.

71, Queen Victoria-street, London, E.C., May 23, 1893.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The controversy on this matter, which is at present going the round of the press, has developed into a form which is neither useful nor instructive, and has no bearing on the actual question involved.

Mr. Dowsing, in your last issue, tries to compare the cost of electrical heating with that of coal, a comparison which is impossible, as the conditions required are totally different. Mr. Dowsing gives no exact figures to calculate from as to the total available heat per ampere hour, and it is possible that the heating apparatus at present used may be greatly improved; the first apparatus designed can hardly be considered as final, although Messrs. Crompton may be fairly credited with the first practically successful attempt to utilise electricity for domestic heating purposes. Taking Mr. Dowsing's own figures, with electricity at 5d. per unit, it requires about 3½ amperes for ten minutes to boil one quart of water, the cost being one-third of one penny. With the water at an initial temperature of 62°F. this gives an expenditure of 375 units of heat in useful work, a cost rate of 1125 units for one penny. The only fuel which can compare with electricity is ordinary coal gas, which can be used under the same conditions and with the same regard to economy in small and irregular work. One cubic foot of coal gas, as supplied in London, has a total heating power of 660 units, and of this, over 600 units are obtained in actual work in many commercial forms of bath heaters; in boiling a small kettle over an atmospheric burner, the average duty in practice will not exceed about 400 units, *i.e.*, less than two-thirds the total theoretical work. If we allow a further margin, and reduce this to 375, one cubic foot of London gas will give at least the work of 3½ amperes for ten minutes, and three cubic feet, costing one-tenth of a penny, will do the work specified by Mr. Dowsing as costing one penny for the electricity used. No doubt, each will have its own place, and will fill certain special requirements, but it is certainly a mistake to attempt to prove that electricity is at present a cheap source of heat. No doubt, the duty actually obtained from coal gas is very much higher than it was at first, and electricity has the very great advantage that its practical application is in the hands of trained experts, and has been so from the first; possibly, no industry in the world has so large a proportion of competent manufacturers and first-class workmen, who understand both the theory and practice of their work.

The application of coal gas as a fuel, on the contrary, has been under a cloud for years. Discouraged by the old proprietary companies, and hampered, as it has been and still is, by want of knowledge of the simplest natural laws on the part of most of the men who have to make and fix the apparatus, it is only now beginning to emerge from a state of chaos; but when it has been thoroughly established on a proper scientific basis, the manufacturers of coal gas will have no more to fear for its future than they have now from the beautiful old moderator lamps, which are so charming and so expensive, in our drawing-rooms and picture galleries. All are not fortunate enough, or rich enough, to have electric lighting, or to put in special ventilators for the removal of the products of combustion. When the purveyors of either gas, electricity, or moderator lamps assume the possession of perfection and infallibility, they only lay themselves open to attacks which are not always tempered with justice or discretion, and which cause a very unnecessary ill-feeling.—Yours, &c.,

Warrington, May 24th, 1893. THOS. FLETCHER, F.C.S.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to Mr. Dowsing's letter in your last week's issue, and to your editorial notes thereon, I beg to point out that what Mr. Dowsing states as to the time taken to boil one quart of water with 3½ amperes at 100 volts must be quite incorrect. The theoretical time required to boil the water alone is 18 minutes from 20°C., and there is the metal of the kettle and the enamel, &c., together weighing several pounds, to be heated in addition, so that at least 20 minutes will be required, even if the apparatus has an efficiency of 100 per cent., which it certainly has not.—Yours, &c.,

LESLIE MILLER.

TRADE NOTES AND NOTICES.

The 1893 Edition of "THE ELECTRICIAN" Electrical Trades Directory and Handbook is NOW READY. This useful book contains over 1,000 pages, and several new and handy features have been added. Price 7s. 6d., post free 8s. 3d.; abroad 8s. 10d. *Comparison with any similar electrical publication is specially invited.*

TENDERS INVITED.—The Borough of Falmouth Urban Sanitary Authority are desirous of receiving offers from companies or firms willing to undertake the introduction of the electric light in the Borough on their own responsibility.

——— The Woolwich District Electric Light Company (Limited) invite tenders for laying cast-iron pipes with inspection boxes, &c., for the mains under the footways of certain streets in the Woolwich District. Specifications can be obtained of Messrs. Pritchetts and Gold, Soho-square, W.

TENDERS ACCEPTED.—The Brighton Corporation have accepted the tender of Messrs. Goolden and Co. for the supply and erection at the electricity works, North-road, of a central-station switchboard and apparatus, the amount of the tender being, as will be seen by the list, less than one-fourth that of the highest :—

Fowler, Lancaster and Co. (Limited), Birmingham	£3,459	0	0
Messrs. Laing, Wharton and Down, London	3,388	0	0
Gulcher Electric Light and Power Company (Limited), London	2,480	0	0
Messrs. Johnson and Phillips, London	2,414	6	0
Poole and White (Limited), London	2,248	12	6
Crompton and Co. (Limited), London	2,231	0	0
Latimer Clark, Muirhead and Co. (Limited), London	1,750	0	0
Thames Ironwork and Shipbuilding Company (Limited), London	1,300	0	0
Siemens Bros. and Co. (Limited), London	1,230	0	0
Messrs. Goolden and Co., Harrow-road, London (accepted)	800	0	0

——— The Governors of the Killarney District Lunatic Asylum have accepted the tender of the Killarney Electric Light Company (Limited) for the installation and supply of electric light to the asylum. The installation is to consist of 324 16-c.p. lamps, and the amount of the tender is £185 per annum.

——— The County Council of Huddersfield have accepted the following tenders :—Mr. A. Sykes, Turnbridge, for the supply and fixing of electric light fittings at the lighting station, St. Andrew's-road; Messrs. Calvert and Co., for the supply of cast-iron exhaust pipes for the boilers at the same station; Messrs. Liversedge and Co., for the supply and fixing of a lightning conductor to the chimney.

——— The Great Northern Railway Company have accepted the tender of Messrs. Johnson and Phillips for the supply of Brockie-Pell arc lamps and accessories for their Holloway electric light station.

CHANGE OF NAME.—By sanction of the Board of Trade, the Electricity Supply Corporation (Limited), of 12, Maiden-lane, W.C., will in future be known as the Charing-cross and Strand Electricity Supply Corporation (Limited).

COMMERCIAL CABLE COMPANY.—This Company issue a well-illustrated pamphlet in connection with the World's Fair at Chicago. Included in the list of illustrations are photographs of the many offices of the Company throughout Great Britain and America.

AGRICULTURAL HALL, LONDON.—We have frequently commented upon the absence of the electric light in this large building, and we shall, doubtless, shortly learn that steps are being taken to instal the light, as the London County Council refused its consent to the letting of spaces under the galleries during the recent Horse Show unless the electric light was used. As a consequence, the spaces, which would otherwise have brought in a considerable rentage, were unoccupied.

THE TRENT GAS ENGINE COMPANY.—This firm have selected, as a method of advertising and introducing their specialities to probable purchasers, a weather almanack, copies of which can be obtained on application to the Company's Nottingham offices.

LONDON AND LANCASHIRE ELECTRIC AND GENERAL ENGINEERING COMPANY (LIMITED).—This Company, in notifying the appointment of Mr. C. N. Russell as their engineer and manager, announce that several important additions to their manufacturing plant have recently been put down, and they are now able to promptly execute orders for Weston dynamos, arc lamps, and general electrical apparatus, as well as metal spinning and light and heavy general engineering.

THE ELECTRO-HARMONIC SOCIETY.—The balance-sheet is issued of this Society, which shows the total number of members at the close of the seventh season at 338, comparing with 155 members in the first season. Application forms for new members can be

Digitized by Google

obtained of the hon. sec., Mr. H. Alabaster, Brockenhurst, Therapia-road, Honor Oak, S.E.

TRAIN DEPARTURE INDICATOR.—We give an illustration of a signal apparatus made by the Allgemeines Elektricitäts Gesellschaft, of Berlin, and designed to prevent the confusion which prevails at many railway termini (especially on the Continent), owing to passengers not being able to readily ascertain the time of departure of their trains. These indicators are intended to be placed in conspicuous positions at the station, and show the destination and time of departure of the train, while a warning is given by the ringing of an electric bell inside the case at intervals of a few minutes before the time of departure. Doubtless railway

officials would be spared incessant questioning and worrying were apparatus of this kind in more general use.

BEDFORD.—A deputation last week waited on the Town Council to protest against the electric light undertaking being placed in the hands of a company, and urging the retention of the powers of the Provisional Order by the Council. A petition signed by 204 ratepayers was presented. Ultimately the petition was referred to a special meeting of the Council for consideration.

DOLGELLY.—The Local Board have received a bill from the local Electric Lighting Company claiming £2,000 for damage alleged to have been done to their lamps. The Board refused to pay the bill.

DOVER.—A satisfactory settlement has been come to between the Town Council and the Brush Company in reference to the lighting arrangements for the town, but as the time for the commencement of operations has expired, a further extension for three months has been agreed to.

DUBLIN.—The branch office of Messrs. Woodhouse and Rawson United (Limited), which has been established here for some time, is about to be closed. The Edison and Swan United Electric Light Company are opening extensive premises in Dawson-street as an Irish depôt for the exhibition and sale of their manufactures, under the supervision of Mr. Boucher.

ELECTRICAL TRADES' UNION.—A meeting of union and non-union men employed in the electrical trades was held on Saturday last at the Black Boy Inn, Newcastle. Very few persons were present. Mr. W. T. Gooday, the general treasurer, addressed the meeting on the eight hours question.

FALKIRK.—Mr. T. Blackadder, of Messrs. Blackadder Brothers, Garrison Foundry and Engine Works, Falkirk, has introduced the electric light into his mansion, the necessary plant being manufactured by the firm. The installation includes storage batteries.

FIRES.—On Wednesday morning the premises of Messrs. Taylor and Tucker, art metal workers, at Harlesden, were burnt to the ground. The damage to the building (of which the walls only remain) and the contents is estimated at £10,000.——On Wednesday some damage was caused to the Woodhouse and Rawson Company's works at Hammersmith by a fire which occurred at the Kensington Stores.

GLASGOW.—The extensive premises of the British Linen Bank, Queen-street, Glasgow, have been completely installed with the electric light by Messrs. Anderson and Munro, of Bothwell-street.

HOTEL LIGHTING.—The first of the Dundee hotels to be lighted electrically is Mather's Hotel, Whitehall-street, Dundee. The work will be carried out by Messrs. Maxwell and Co. The Royal Hotel is to be similarly lighted as soon as the alterations are completed.——At Windermere, Riggs', The Old England, Crown and Bellsfield Hotels have been lighted by electricity, and it is expected that the public lamps will be in working order almost immediately.

HOUSE LIGHTING.—Mr. John Paddons has recently installed the electric light at his residence, St. Sidwell's, Sydenham Hill, S.E., the light being used throughout the house and stables in the rear. The fittings, which are of exceptionally artistic design, were supplied by Messrs. Evered and Co. and Messrs. Richard Crittall and Co.

HUDDERSFIELD.—In connection with electric lighting, a special sub-Committee of the County Council have visited Sheffield, and have examined the system of electric lighting in that city. Mr. J. A. Crowther has been appointed mechanical engineer in connection with the electric lighting department. Tenders have been accepted by the Council, particulars of which will be found in a previous column. At the last meeting a question was asked as to why the sub-Committee had found it necessary to alter the arrangements previously come to with the Brush Company, and Councillor Garton, in explanation, said that, at the time those arrangements were made, the Committee prepared a schedule of prices. They had received more applications for the electric light than had been anticipated, and when the Committee applied for the additional supply, the Brush Company asked more than the Committee considered they were entitled to by this schedule of prices. The plant originally put down was not sufficient for the demand upon it, although sufficient to start operations with. The report of the Committee was adopted.

LEICESTER.—The Midland Railway Company are putting down a Dowson gas plant in connection with their electric lighting installation at the new Leicester Station. Crossley gas-engines are to be used.

SHEFFIELD.—The Sheffield Electric Light and Power Company (Limited), having now nearly completed the laying of their underground mains throughout the compulsory lighting area, have opened a large show room for electric light fittings and apparatus at 27, Church-street, Sheffield, under the charge of Mr. M. B. Cotterill.

SHREWSBURY.—As mentioned in our last issue, the Local Gas Company has intimated to the Town Council their intention to increase the price of gas supplied to the public lamps. A long discussion upon the subject took place at the last meeting of the Council, during which it was pointed out that the Gas Company had enjoyed great prosperity for many years, and that they were thus pursuing an unwise policy in exacting higher rates for the gas than previously, because they were unable to keep up the statutory 7½ per cent. dividend. Mr. Barker, the Chairman of the Gas and Lighting Committee, said that the Committee would undertake to give the subject of electric lighting their best attention.

TRAMWAY LIGHTING.—The Dundee Tramway Company have commenced a series of experiments in lighting their cars by electricity. Paraffin lamps are at present used, and we understand that the question of substituting the electric light is only one of arrangement between the Gas Commissioners and the Tramway Company as to the terms for charging the batteries.

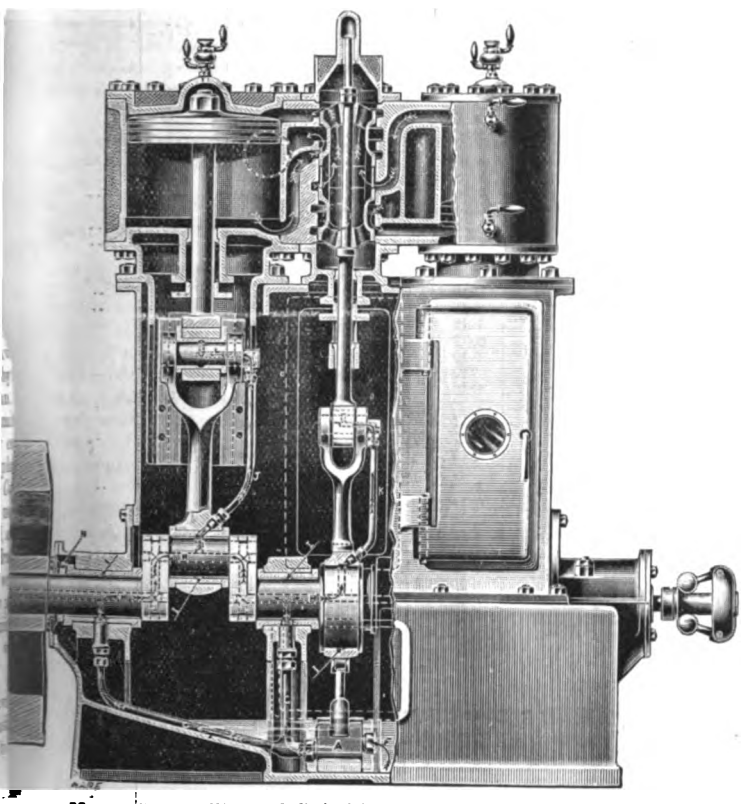
WATFORD.—The Local Board have finally decided to apply for an Electric Lighting Provisional Order.

WINDSOR.—Messrs. Laing, Wharton and Down have appointed Mr. Dunning, of 6, Clifton-villas, Devereux-road, Windsor, their resident representative. Considerable extension of private electric lighting has recently taken place in the district.

WOLVERHAMPTON.—The Lighting Committee have met to consider the applications for the post of electrical engineer in connection with their electric lighting scheme, and the names of Mr. Baynes, of Bradford, and Mr. Lewis, of Hull, are those from whom the final selection will be made.

Digitized by Google

MESSRS G. E. BELLISS AND Co.—We have to acknowledge the receipt of a handsome catalogue from this firm, containing a number of excellent illustrations of the specialities for which they have attained well-merited success. Among the numerous illustrations included in the catalogue will be found electrical fans, gas compressers, and a variety of electric light engines of several types, including those supplied for the Cunard vessels. On pages 12, 13A, and 13B a full description is given of the Belliss patent double-acting, high-speed noiseless engine, for which, among other advantages, simplicity, durability, economy and steady running are claimed. The engines described in the list are suitable for many purposes, and on pages 43, 44, and 45 are shown illustrations of special steam-launch machinery, for which Messrs. Belliss and Co. have received many orders. The catalogue consists of 60 large 4to pages, and reflects credit alike upon the compilers, engravers and printers. How much good engravings contribute to the success of



Messrs. G. E. Belliss and Co.'s "Crescent" Type Compound Double-acting High-speed Noiseless Engine.

an engineering catalogue was never better shown than in the list under review, and Messrs. Hare and Co. have seldom produced better work, as will be seen on reference to the illustration we give above.

COMPANIES' MEETINGS AND REPORTS.

Telephone Company of Ireland (Limited).

The fourteenth ordinary general meeting is to be held at the offices, Commercial-buildings, Dame-street, Dublin, to-morrow (Saturday), the 27th inst., at 12 noon.

Included in the business of the meeting will be the consideration and, if approved, the passing of a resolution as follows:—

"*That the provisional agreement submitted to this meeting for the transfer of the undertaking of this Company to the National Telephone Company (Limited)—which agreement is dated May 11, 1893, and made between this Company of the one part and the National Telephone Company of the other—be and the same is hereby ratified, and that the Directors be and they are hereby authorised to carry out the said agreement, with such modifications (if any) from time to time as they may deem expedient.*"

In their report the Directors state that during the year there has been an increase of 63 subscribers, and that the account shows a balance to the credit of net revenue sufficient to pay the arrears of dividend upon the preference shares and a small dividend upon the ordinary shares, but that, owing to the necessity for a large expenditure of capital account, the Directors are unable to recommend that any portion of the earning shall be distributed amongst the shareholders. It is proposed to renew the whole of the internal arrangements of the Company's exchanges in Dublin, Cork, Limerick, Dundalk and Drogheda, and to replace the present switch-boards by others of the latest construction. Owing to the fact that the preference shares of the Company which were offered in January, 1890, and also that the debentures offered in July of the same year, were not taken up by the shareholders, the Directors were compelled to incur a large expense, as was shown in the accounts for 1891, and they have been forced to the opinion that an amalgamation with the National Telephone Company would be most advantageous in the interest of the shareholders. Accordingly, the agreement above referred to has been entered into, subject to the shareholders' approval. By this agreement the National Company offers £81,300 for the assets of the Telephone Company of Ireland, and walve any claim to participate in the assets of the Company in respect of the moiety of the ordinary share capital to which they are entitled. These terms the Directors consider fair, and recommend their acceptance. After paying off the debentures and preference share capital (amounting to £61,197), £20,103 would remain for division among the ordinary shareholders, subject only to the arrears of preference divided to December 31st last, and the expenses of liquidating the Company. A large proportion of the preference shareholders have consented to the arrangement with the National Company, on condition that they receive 20s. per share in full discharge of principal and arrears of dividend. Under the agreement referred to with the National Company the interest upon the debentures, and the dividend upon preference shares accruing since January 1st last, are to be borne by the National Telephone Company. Alderman Dillon, Chairman of the Company, retires, and is eligible for re-election; and the auditor, Mr. J. M. Kean, also seeks re-election.

Reuter's Telegram Company (Limited).

The following is the Director's report to be presented at the twenty-ninth ordinary general meeting of the shareholders, to be held at the offices, 24, Old Jewry, London, on Wednesday next, the 31st inst., at 12 noon:—

The Directors beg to report that the net profits for the year ended December 31st last, after payment of current expenses, and deducting rebate or unexpired subscriptions, amount to £3,567. 0s. 10d., including £98. 17s. 4d. brought forward from the last account. In accordance with the Articles of Association, which authorise the appropriation of the reserve for the purpose of equalising dividends, the Directors have transferred the sum of £1,500 from that fund to the profit and loss account, making the total amount available for distribution £5,067. 0s. 10d. The usual interim dividend of 2½ per cent was paid in October last, and the Directors now declare a further dividend of 4s. per share, making a total distrbution, free of income-tax, of 5 per cent. for the year. This will absorb £4,814. 1s. 2d., and leave a balance of £252. 19s. 8d. to be carried forward. The dividend warrants will be payable on the 3rd proximo.

A resolution will be submitted to the meeting authorising the Directors to augument the annual grant made to the Officers' Life Insurance and Superannuation Fund established in 1881, in order that effect may be given to the portion of the scheme dealing with superannuation.

In conformity with the Articles of Association, Mr. Frederick J. Griffiths retires from the Direction, but, being eligible, offers himself for re-election. The auditors, Messrs. Welton Jones and Co., also offer themselves for re-election.

CITY NOTES, &c.

ALLIANCE ALUMINIUM COMPANY (LIMITED).—A meeting is to be held at Messrs. Powell and Burt's, 28 and 29, St. Swithin's-lane, London, E.C., on June 26th, at 12 noon, for the purpose of receiving the liquidator's account of the winding up.

BOY MESSENGERS AND ELECTRIC CALL COMPANY (LIMITED).—Notice is given that the creditors of this Company (in voluntary liquidation) are required to send their names and addresses, and the particulars of their debts or claims, to the liquidator, Mr. Montague Pawson, 58, Coleman-street, London, E.C., on or before June 5th.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended May 21st were £794, as against £766 for the corresponding period of last year, being an increase of £28. The total receipts for the half-year amount to £17,735, against £16,374 in the corresponding period of 1892, being an increase of £1,361.

MARTINY (LIMITED).—Notice is given that the first annual drawing of the Five per Cent. First Mortgage Bonds of this Company will take place at the offices, 37, Lombard-street, on June 30th, at 3 p.m., when bonds to the amount of £2,000 will be drawn.

METROPOLITAN ELECTRIC SUPPLY COMPANY (LIMITED).—This Company give notice that the coupons due on June 1st on the £50,000 Five per Cent. Registered Debentures (Bonds 1 to 5,000) will be paid on and after that date at Messrs. Prescott's Bank, 50, Cornhill, or at the Royal Bank of Scotland, 123, Bishopsgate-street (Within), E.C. The coupons must be left at the bankers three days for examination.

NATIONAL TELEPHONE COMPANY (LIMITED).—Letters of allotment and regret have been posted in respect of £273,523 of the Four and a-Half Per Cent. Debenture Stock, which was recently offered to the ordinary shareholders of the Company.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee have appointed Tuesday next, the 30th inst., a special settling day in the following securities, which are also to be quoted in the Official List:—Charing Cross and Strand Electricity Supply Corporation (Limited), 20,510 shares (Nos. 1 to 6, 215 to 718, and 10,001 to 30,000); Pacific and European Telegraph Company (Limited), £100,000 Four per Cent. Guaranteed Debentures (Nos. 1 to 1,000).

Digitized by Google

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended May 19, 1893, after deducting 17 per cent. of the gross receipts, payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,680.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED.)—The receipts for the two weeks ended May 15th were £4,000, as compared with £2,663 for the corresponding period of last year. January receipts estimated at £5,568, realised £5,647.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 785.—Vol. XXXI. FRIDAY, JUNE 2, 1893. PRICE FOURPENCE.
Annual Subscription (U.K.), 19/6

NOTES.

The new engineering and electrical laboratories of University College, which were "opened" by the Duke of Connaught on Monday last, will, when they are equipped and ready for use, form an important addition to the means for teaching the scientific principles of engineering. An article by Dr. Fleming and Hudson Beare in a descriptive pamphlet, as well as a paragraph in a circular of the Department of Applied Science and Technology, distinctly state that "it should be clearly understood that the education given in this Department of the College is not intended to supersede such necessary practical training as can only properly be acquired in the workshop or factory." The buildings, which are not yet completed, will contain a considerable number of different rooms and laboratories. The arrangements appear to be most carefully worked out, both as to the accommodation for a great variety of work and in the details of the fittings. The laboratories give every promise of being worthy of a College which was the first to teach the science of engineering, and the first in this country to establish, under Prof. Kennedy, an engineering laboratory.

Useful as the results of a properly-directed course of applied science may be to the students for whom these laboratories are primarily intended, we may confidently expect that valuable original work will be done, not in the ordinary course of teaching, but by the professors and their staff. Experiments carried out in collaboration with other departments—for example, the relation between the magnetic hysteresis and permeability, and the mechanical properties of iron under stress—together with the chemical constitution of the specimens, is a subject which might be most usefully dealt with in such a laboratory.

The "elevated tone," to use the words of an engineering contemporary, that Mr. J. B. Thacher, Chairman of the Awards Committee of the Chicago Exhibition, has endeavoured to impart to the ever-burning question of exhibitors' medals, &c., does not appear to be appreciated in the proper quarter. A Reuter's telegram, dated Chicago, May 27th, reads as follows:—

> The controversy over the system of giving awards at the World's Fair has taken a surprising turn. The Commissioners of the foreign countries represented have decided to enter into competition amongst themselves, to establish a board of jurors independent of those in the American section, and to issue diplomas without regard to Mr. Thacher, President of the Bureau of Awards. The position is very embarrassing. The awards granted by the foreign Commissioners, who have now withdrawn, will, under present circumstances, be the only evidence of international competition, for the South American Republics are expected to join the movement. Mr. Thacher will, therefore, be left with nothing but the American section to deal with.

The scheme, which has added yet another to the many unedifying squabbles connected with the Chicago Exhibition, in so far as it is a distinct departure from the discredited system hitherto in vogue, deserves the support of all who desire to see an end put to the imposture of granting certificates of industrial virtue without inquiry; and we trust that a half-way house will yet be found between the Thacher and the jury system. The proposal of the Chairman of the Awards Committee was that each and every exhibitor should be given a bronze souvenir medallion as an evidence of participation in the Exhibition, and that deserving exhibitors should receive a report, signed by an expert judge, setting forth the merits of the exhibits, without "odorous comparisons." Against the Thacher scheme, of course, objections may be made; and unless all the experts be men entirely above suspicion, not only of corruption but of favouritism, the results would be even worse than those of the jury system; but no doubt the real *raison d'être* of the present uprising is that we are not as yet educated up to the height of subordinating the commercial advantage of the individual to any other consideration.

According to a telegram, dated Chicago, May 31st, Mr. Thacher has partially yielded to the pressure brought to bear upon him by the foreign exhibitors, and has modified his rules governing the question of awards. He has addressed a letter to the foreign Commissioners, informing them that, in accordance with their request, two or more judges or examiners would be appointed to inspect individual exhibits.

A decision recently given in an action brought by the Edison Company against the Equitable Life Assurance Company of New York is one that we should very much like to see repeated in this country. The owners of a patent sought to recover damages against a private user who happened to be in possession of certain electric light fixtures covered by their patent. The judge held that as the plaintiffs had for eleven years acquiesced in the alleged infringement, they had forfeited all right to recover. The raking-up of forgotten patents and the annoyance of unwitting private infringers are two abuses which should be rendered impossible whenever our own Patent Code again comes up for revision.

Messrs. J. H. Holmes and Co., of Newcastle, have sent us a report by Prof. Kennedy on their dynamos, which we described last week. The figures tend to corroborate the report which has been already published; the combined efficiency being 85·6 per cent. instead of 86·04 per cent., and the steam per electrical horse-power 20·3 instead of 21·66lb. The rise of temperature of the armature was given as 44·7°F. in the previous report, but Prof. Kennedy, by inserting a thermometer with a small bulb well into the end of the armature, found a temperature of 132·5°F., showing a rise of 72·0°F. after a six hours' run. When a temperature limit was first included in the Admiralty specification, contractors were left in ignorance as to the mode in which the temperature would be measured, or, rather, in which an attempt would be made to measure the temperature of some part of the machines. Between the laying of a thermometer against the outside of an armature, with the application, perhaps, of a piece of waste outside, and the measurement of the resistance of the armature circuit, there is room for a great difference. Nothing could be more easy and less accurate than the former, while exactly the reverse might be said of the latter. Prof. Kennedy's plan of probing with a small thermometer is an excellent one, but perhaps dynamo builders who find a difficulty in keeping their armatures cool will endeavour to avoid leaving a suitable hole for such a test. The obvious result would be that a demand should be made in specifications for such a hole, if it is proposed to adopt this method. Some curves giving the efficiency for different loads, the "Willans law" lines of steam consumption, and the steam per E.H.P. hour and I.H.P. hour, accompany Prof. Kennedy's report, but we received them yesterday too late for publication.

Mr. J. Erskine Murray's determinations of the electro-chemical equivalent of zinc, which are given elsewhere in the present issue, constitute a useful contribution to our knowledge of natural constants. The difficulty in obtaining a coherent deposit of many metals that can be separated by the electrolysis of their aqueous solutions, makes the direct comparison of their equivalents no light task, especially when, as in the case of zinc, the high heat of combination of the metal, and the ease with which it is superficially oxidised, have to be considered and provided for. It is interesting to note that the best-looking deposits were got when the cathodes were used soon after they had been polished, indicating that superficial oxidation, scarcely discernible by any other means, occurs within a short period after cleaning. The known difference of the ease of attack of pure and commercial zinc suggests a question as to the quality of the zinc used by Mr. Murray for his plates. The purest metal that has been hitherto prepared is that produced by the fractional distillation *in vacuo* of approximately pure zinc contained in a glass combustion tube—an operation less formidable than it sounds. Should zinc, contaminated with such an impurity as lead or cadmium, have been used, the occurrence of the light brownish film observed on the parts of the plate bearing no appreciable deposit would be explained, even assuming that the electrolyte consisted originally of pure zinc sulphate.

Another result of importance is the possibility of calculating the atomic weight of zinc from Mr. Murray's figures. The comparison has fortunately been made with copper, and the atomic weight of copper has lately received much attention. Taking the value obtained by Prof. Mallet for copper, which is 63·6 very approximately, the atomic weight of zinc becomes 65·5, oxygen (16) being taken as the standard in each case. This value for zinc is higher than that commonly adopted by 0·5, but there still exists some uncertainty in the matter, and the tendency of recent work is to show that Zn = 65 is lower than the truth. A direct comparison made some years ago by Lieut.-Colonel Reynolds and Prof. Ramsay between zinc and hydrogen gave Zn = 65·48, corresponding nearly to 65·63, when oxygen is taken as 16 instead of 15·96, the figure generally accepted at the time of the investigation; so that it may well be that when the atomic weight of zinc is known with as much accuracy as that of silver, Mr. Murray's result may be found nearer the truth than others at present assumed to be correct.

The Hanover Central Station, designed and equipped by Messrs. Schuckert and Co., is an interesting example of Continental practice in continuous-current work. In the description of this station, which will be found in another column, it will be observed that larger units of plant are employed than is customary in this country. Makers of large engines have not published any exhaustive tests of steam consumption on short runs and variable loads, and there does not at present appear to be any reason for supposing that these engines offer any advantage in economy of steam for such work. If an engine for some 500 or 600 horse-power must be built, the type adopted at Hanover is, no doubt, an excellent one. A breakdown of such engines is, however, so serious a matter that there is a tendency to run them at rather lighter loads than is customary with smaller sizes. In comparing these large dynamos, having 6ft. 6in. commutators, with the continuous-current dynamo commonly used in English stations, it would seem that while, perhaps, there is not a greater total number of brushes in the former case than in the latter, the setting and care of the brushes on these multipolar machines must require a good deal of attention. The drawing of such an armature for repair, and the renewal of the commutator, must be a serious matter.

According to the usual custom, the candidates selected by the "Council of Candidates" of the Royal Society were elected yesterday afternoon. Opposition had been roused within a few days of the election on the ground that one of these candidates was unworthy of this scientific distinction, and another name was suggested by certain Fellows. The wide range of science represented in the Royal Society cannot but give rise now and then to a feeling that one branch is inadequately honoured. It is difficult for a physicist to estimate the value of physiological researches on the functions of an unheard-of organ of some insignificant beetle; and the exact point at which trifling becomes dilettantism, and at which the dilettante is an ornament to the science which he patronises, must always be hard to decide.

Digitized by Google

Automatic Signalling.—The Board of Trade has sanctioned the use of the automatic signals on the Liverpool Overhead Railway.

Yarmouth.—The Ratepayers' Association and other ratepayers have drafted petitions against the electric-light scheme adopted by the Corporation, and are placarding the town.

The Salomons Scholarship.—A Salomons Scholarship of £35 has been awarded to each of the following students:—Francis R. Lydall, of King's College; and J. T. Morris, of University College.

Cable Interruptions:—

	Date of interruption.
Paramaribo-Cayenne	April 15.
Santiago de Cuba—Mole St. Nicholas	April 20.
St. Thomé—Loanda	May 30.

The Mercer Fund.—The subscription list for this fund being closed, the Committee are anxious to invest the proceeds as soon as possible, and will therefore be glad to receive the subscriptions promised, which can be sent to the treasurer, Mr. J. Reeves, 3, Bank-buildings, Hastings.

Royal Society.—The following Papers were down for reading yesterday:—Capt. Abney, F.R.S., "On the Colour of Skylight, Sunlight, Cloud-light, and Candle-light"; A. W. Porter, "Note on the Flow in Electric Circuits of Measurable Inductance and Capacity; and in the Dissipation of Energy in such Circuits."

Electrical Bills in Parliament.—The Examiner of Standing Order Proofs in the House of Lords has passed the following Bills:—Electric Lighting Provisional Order (No. 5), Electric Lighting Provisional Order (No. 6), Electric Lighting Provisional Order (No. 1), Electric Lighting Provisional Order (No. 3), Barry Railway.

Wolverhampton Municipal Electrical Engineer.—At a meeting of the Wolverhampton Town Council Lighting Committee on Tuesday, Mr. F. Harman Lewis, electrical engineer to the Corporation of Hull, was appointed to a like position under the Wolverhampton Corporation, at a salary of £300 per annum. There were 36 candidates.

Paris and New York Telegraph Company.—As a result of the recent litigation, says Dalziel, the new Board of Directors of the French Cable Company will be composed as follows:—Marquis de Lauris, Messrs. Chauvassaignes, Decarrere, Lefevre, Pestel, Etard (Administrateur), Bouillaire, de la Beaumelle, Cibiel, Lafargue, and Solomon Halphen.

The Late Prof. Couch Adams.—The Bishop of Truro, on Saturday last, unveiled a new tablet erected in Truro Cathedral to the memory of the late Prof. John Couch Adams, of Cambridge. The tablet was designed by Mr. Pearson, R.A., and executed by Mr. Juleff, sculptor, of Cornwall. The cost of the tablet has been defrayed by public subscription.

Ocean Telegraphy.—A telegram has been received at New York from Chorillos, in Peru, stating that the laying of the duplicate cable of the Central and South American Telegraph Company was completed on Monday. The new cable is 2,524 miles in length, and extends from Salina Cruz, in Mexico, to Chorillos, a port near Lima. It was manufactured by the India Rubber, Gutta Percha and Telegraph Works Company, at Silvertown.

Telegraph Communication with the Azores.—The statement which has appeared in *The Times* and other papers that the negotiations for a submarine cable between Lisbon and the Azores have been finally concluded is somewhat premature, as negotiations are still going on, there being one or two minor points still left unsettled. It is expected, however, that in a few days the business will be completed, and that the cable will be laid by the Telegraph Construction and Maintenance Company, on behalf of the Eastern Telegraph Company, some time in September.

Telegraph Extension to the Mauritius.—The vote for the subsidy in respect of a cable to connect Seychelles and Mauritius with the Eastern and South African Telegraph Company's system at Zanzibar having been approved by the House of Commons, the cable is being manufactured, and will be laid by the Telegraph Construction and Maintenance Company before the end of the year. This important addition to the Eastern Telegraph Company's system has long been contemplated, and will confer a great boon upon the Mauritius, which has much felt its isolation in a telegraphic sense, besides adding an important link to the already very extended network of telegraphs in Eastern seas.

Electrical Trade Section.—A meeting of the Electrical Trade Section will be held at Botolph House, Eastcheap, at 3.45 p.m. to-day. A full attendance is particularly requested. The agenda are as follows:—(1) Minutes; (2) Overhead Wire Regulations (position of matters up to date of meeting); (3) Electric Traction (to consider a motion, notice of which has been given, that a Special Committee of the Section should be appointed with power to raise funds and take such other action as may be necessary to promote the interests of electric traction); (4) Railway Rates (to consider the desirability of representations being made to the Railway Association that a special rate should be granted for the carriage of electrical wire and cable); (5) Other matters.

Lightning.—A fishing boat arrived at Newhaven on Thursday morning of last week in a considerably damaged condition from the effects of lightning. While lying in harbour, the boat was struck by lightning. The first contact seemed to have been at the masthead, and the current, passing down the steel-wire jibhalyards, went completely through the boat's gunwale, leaving an opening about 9in. wide. On the other side of the boat part of the gunwale was torn away for about 10ft. to 12ft. The wire rope immediately above the clip-hooks was entirely consumed. On Monday last, during a thunderstorm at Lewes, a Corporation *employé*, whilst at work with another man at the Corporation Wharf in North-street, was struck by lightning and sustained an injury to his eyes.

The Popp Company.—*L'Industrie Electrique* states that the system of electrical distribution adopted by the Popp Company, now the Compagnie Parisienne de l'Air Comprimé, is about to be completely reorganised, MM. Cuenod, Sautter et Cie. having contracted to lay down a plant similar to that in use at Genoa. At the Rue St. Fargeau central station there are to be three 275-ampere, 1,100-volt Thury dynamos connected in series. These machines will supply current to 21 Thury continuous-current transformers, of which 13 will have an output of 300 amperes, and eight of 600 amperes at 115 volts. These transformers will charge accumulators from which the lamp current will be taken. The Popp system seems unable to disassociate itself from roundabout methods. The new plant is to be in working order by October 1st.

"Telegraph Cable Lodge."—A masonic lodge, under the above title, was consecrated on the 30th ult. at the "Ship and Turtle," Leadenhall-street, E.C., by the Grand Secretary, Mr. E. Letchworth, assisted by Messrs. T. Fenn, J. C. Parkinson, Frank Richardson, Sir George Harris, and the Rev. J. Brownrigge. The Marquis of Tweeddale was installed as first Master, with Sir George Elliot, Bart., and Major Alexander Wood, as Senior and Junior Wardens. The other offices were filled as follows:—Treasurer, Mr. T. A. Bullock; Secretary, Mr. W. T. Ansell; I.P.M., Mr. F. Moll; S.D., Mr. W. Hibberdine; J.D., Mr. F. Weniger; I.G., Dr. Wholey; D.C., Mr. C. B. Barnes; and W.S., Mr. O. Moll. A large company, including Lord Cremorne and many other grand officers, sat down to the banquet which followed.

The City Lighting.—At the last meeting of the Commissioners of Sewers Mr. Morton brought under the notice of the Court the fact that the Press Association premises in New Bridge-street, which had been fitted at great cost, remained unlighted by electricity, and he asked why the private electric lighting in the City had been so long delayed. Mr. Morton concluded by moving that the Company should be communicated with on the subject. This motion, having been seconded, was adopted. It was also resolved, on the motion of Mr. Johnson, to instruct the Streets Committee to prepare a report upon the subject of laying telephone tubes in conjunction with the electric lighting arrangements. On the motion of Mr. Barham, seconded by Mr. Smallman, it was decided to communicate with the Electric Lighting Company on the subject of the space it was utilising in the City for transformer stations.

Personal.—Mr. Sidney H. Wells, Wh.Sc., Assoc.M.Inst., C.E., Assoc.M.Inst., M.E., of the Yorkshire College, Leeds, has been appointed Principal of the Battersea Polytechnic Institute. Mr. Wells was formerly assistant master on the engineering side of Dulwich College, and, in addition to scientific education, has had the advantage of a practical training in the works of Messrs. Maudsley's, Westminster.—Mr. Cawley, who has been chief editor of *Industries* since our contemporary was started some seven years ago, is about to retire, but not before gaining for *Industries* an established position in the field of technical journalism. At the beginning of this year a change occurred in the proprietary of our contemporary, and this, we understand, led to Mr. Cawley tendering his resignation. After concluding his editorial work he intends carrying on business as consulting engineer, and has taken offices at 29, Great George-street, Westminster, S.W.

Institution of Civil Engineers.—The annual general meeting of this Institution was held on Tuesday last. The gross numbers on the books on March 31 in 1892 and in 1893 were 6,239 and 6,397 respectively. The total receipts for the year 1892-93 amounted to £25,276. 19s. 2d. The general expenditure has been £16,527. 17s. 6d. (including £7,750 for publications and for premiums under Trust, £522. 2s. 10d.); while there has been invested £8,254. 12s. 2d. The summary of investments show that there stand to the credit of the Institution £111,400, with Trust Funds of the par value of £15,606 0s. 10d., together £127,006. 0s. 10d. The ballot for Council resulted in the election of Mr. Alfred Giles, as President; of Sir Robert Rawlinson, Sir B. Baker, Sir Jas. N. Douglass, and Mr. J. W. Barry as Vice-Presidents; and of Dr. W. Anderson, Mr. A. R. Binnie, Sir Douglas Fox, Sir Chas. A. Hartley, Messrs. J. C. Hawkshaw, C. Hawksley, and Alex. B. W. Kennedy, Sir Bradford Leslie, Mr. J. Mansergh, Sir Guilford Molesworth, Mr. W. H. Preece, Sir E. J. Reed, and Messrs. W. Shelford, F. W. Webb, and W. H. White, as other members of Council.

Obituary.—Dr. Franz Stenger, who recently succeeded the late Dr. Lowenherz as Director of the Physikalisch-technische Reichsanstalt at Charlottenburg, died on the 21st ult., at the early age of 34 years. Dr. Stenger was for some time Professor of Electricity at the Technische Hochschule of Dresden.——We have also to record the death, on the 23rd inst., of Samuel Elkins Phillips, F.C.S., in his 80th year. He was associated with the late Dr. Whitehouse in the early days of the first Atlantic Cable project. Later he was appointed superintendent of the Benghazi Station on the line connecting Malta and Alexandria, *vid* Tripoli and Benghazi. On returning to England he was appointed by the Government one of the superintendents who were sent out with the Persian Gulf Cable, and in this capacity was in charge of the Bushire Station.——Mr. A. W. Meston, the inventor of the Meston alternating-current motors, a brief description of which we gave in our TRADE NOTES of May 19th, recently died at his residence, St. Louis. Mr. Meston was a Scotchman by birth. He went to America, when a lad of 14, and studied electrical engineering at the Washington University. His special study was that of adapting small alternating-current motors for use on single-phase circuits.

The American Institute of Electrical Engineers and Visitors to the Chicago Exhibition.—The following letter from the Secretary of the American Institute of Electrical Engineers has been received by the Secretary of the Institution of Electrical Engineers :—

MY DEAR SIR: I take much pleasure in informing you that the World's Fair authorities have placed at our disposal two rooms adjoining the official head-quarters in the Electricity Building at Chicago, which I am expected to occupy as the head-quarters of the Institute during the Exhibition season. The rooms will be fitted up with all essential conveniences, and the Members of the Institution of Electrical Engineers will be welcome there at all times. Letters may be forwarded in the care of the Institute, and I shall be pleased to be of any possible service to our visitors. The house of the American Society of Mechanical Engineers, at 12, West Thirty-first-street, New York City, where our regular head-quarters are established, will also be available to your members while in this city. Arrangements are now being perfected to make it a general bureau of information for visiting engineers, and a special invitation has been extended to friends of the American Institute of Electrical Engineers and the American Institute of Mining Engineers, to consider the house of the Mechanical Engineers their resort for such facilities as it affords. It is conveniently located in respect to the finest hotels and theatres, and with elevated railway and cable tramway facilities to other parts of the city. Trusting we may have the pleasure of meeting many of our European friends during the season,—I beg to remain, yours very truly, RALPH W. POPE.

New American Wiring Rules.—"The uncalled-for mystery surrounding the discussion and promulgation of the fire-underwriters' rules that have been under consideration since last August has," says the *Electrical World*, "finally been dispelled." These new rules, which have now been submitted to the various companies concerned for adoption, are the result of the deliberations of underwriters' experts held in New York last August and December, whose meetings also resulted in the formation of the Underwriters' International Electric Association. Among the features of the new rules are the prohibition, by implication, of wooden cleats and the requirement that all telegraph, telephone and similar conductors shall be provided with some protective device where they enter a building. All safety fuses must be stamped or otherwise marked with the number of amperes they will carry. Another prohibition is that of multiple-series lighting. The smallest wire that can be used outside conduit tubing and fixtures has been reduced from 16 B. and S. to 14 B. and S. The use of staples is absolutely prohibited. Taken as a whole, the rules," says our New York contemporary, "are characterised by sound common sense, and show a due appreciation of the interests of those to whom they are to be applied. Their general adoption now rests with the various insurance companies and associations interested in electrical risks, and it is most sincerely hoped that these bodies will take speedy action toward their adoption, and thus remove a reproach to electrical inspection which has heretofore existed, on account of the number and disparity of independent rules in existence."

Telephone Poles at Broughty Ferry.—What, says the *Dundee Courier*, is to be the upshot of the dispute pending between the Broughty Ferry Police Commissioners and the Telephone Company, is a question that is at present engaging a good deal of attention in the burgh. The time fixed by the Commissioners for the Company to make an acceptable offer to them for wayleave is now rapidly expiring without an agreement being come to, and therefore interest in the question is daily deepening. Naturally subscribers are not viewing with equanimity the prospect of losing the telephone service with which they have been accustomed, and news of a settlement would be welcomed by them. The general public have no such interest in the continuance of the service; the action of the Commissioners in endeavouring to tap the Company meets with approval; and from the offer made by the Company it hardly needs to be pointed out that the Company has admitted the principal of payment to the Board to be right. Inadequate as the offer of the Company is considered by the Commissioners to be, it is, we understand, the utmost that will be given, and that the Company have resolved to adhere to their previously-declared purpose of striking Broughty Ferry off the system rather than yield. Equal firmness on the part of the Commission means, therefore, that after June 14th next telephonic communication between Broughty Ferry and the outside world will be suspended. Then will have arrived, if not before, a period of agitation and trouble that will try the nerves of many in the burgh.—A representative deputation of subscribers attended a meeting of the Broughty Ferry Commissioners on Monday night last. It was explained on behalf of the deputation that they had no wish to do anything to weaken the hands of the Commissioners in their negotiations with the Company, but it was pointed out that great inconvenience would be entailed by the closing of the system in the burgh. The position, from the Commissioners' point of view, was explained to the deputation, and it was also pointed out that though the Commissioners insisted upon the removal of the poles from the streets in the event of the Company refusing to pay for them, there was thereby no compulsion on the Company to resort to the extreme step of closing the whole system in the burgh, as it would still be open for the Company to treat with private parties for situations for the poles the same as has been already done in other cases. The outcome of the Commissioners' deliberations was that they resolved to ask a rent of 10s. per annum for each pole, and three free instruments. There being 54 poles on the streets, the total sum would thus be £27.

ELECTRICITY AS A MOTIVE POWER.*

BY ALBION T. SNELL.

(*Continued from page 32.*)

§12. Practical Example of Preceding Method of Design.

The application of the principles of dynamo and motor design, described in the preceding sections, is fairly illustrative of the ordinary methods followed in most drawing offices, but the details are varied to suit the fancy or necessities of each engineer.

The design has been treated in a general way so as to include as many cases as possible, and hence appears to be complicated. In practice, however, owing to fixed types of field magnets, definite sizes of armature plates, and data from machines already built, it is very simple. A machine can be designed for a given output at the required speed in a very short time; indeed, nearly all of the calculations will be in simple proportions that can be seen at a glance on a slide rule.

However, to illustrate the use of the equations the following calculations for a 25-unit dynamo and a 25-B.H.P. motor are appended.

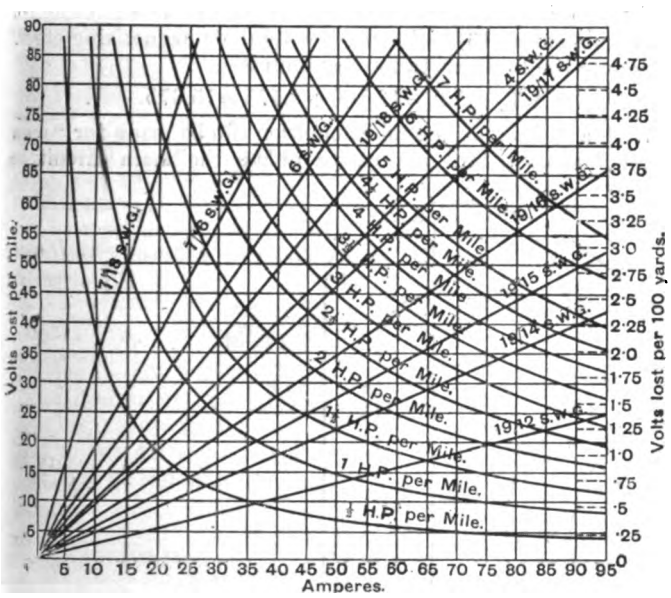

PLATE II.—Curves showing Volts lost per Mile and per 100 Yards with different Currents and usual Sizes of Cable. Calculated from the formula—E = (·0427/area) C. Also H.P. lost per Mile.

It is assumed that the problem is to build a pair of machines to transmit 25 B.H.P. a distance of one mile from the dynamo. Since there is only one motor, the series winding will be most suitable for both machines, this arrangement giving fairly good speed regulation of the motor for variable load if the generator speed be kept constant.

The efficiency of the motor may be safely taken at 90 per cent., and, therefore, the watts absorbed by it at full load will be

$$\frac{25}{\cdot 9} = 28{\cdot}32 \text{ E.H.P.}$$

If the line loss be fixed at 5 E.H.P., the output of the dynamo will be 33·32 E.H.P. = 24,857 watts. On referring to Plate II., which gives the volts and horse-power lost per mile of cable, with different currents and areas, it is seen that a wire of sectional area corresponding with No. 6 S.W.G. will carry 35·75 amperes with a drop of 52 volts and a loss of 2·5 E.H.P. per mile. This is a convenient size wire, as small as it is practically safe to erect for a permanent line and not too costly; it weighs 589lb. per mile, and has a resistance of 1·4694 ohms for the same length. The two miles of line wire will therefore have a resistance of 3 ohms nearly and the fall of potential will be 104 volts, and the watts lost in it 3,730. Dividing the dynamo output by the current (35·75 amperes), the potential difference is seen to be approximately 695 volts. Since the tension is high the armature winding will be of the gramme type, and the double magnetic circuit two-pole field (Fig. 4) will be selected for both machines. The armatures will be made interchangeable in order that one "spare" will cover the two machines; and the field carcases will also be identical save in respect of the number of ampere-turns, and perhaps the area of the magnet cores.

Determination of Armature dimensions.—

From $l\ D^2\ n\ 0\ 01$ . . . . . (1)

$$15 \times 15^2 \times 800 \times 0{\cdot}01 = 28{,}000.$$

Where $l = 15$, $D = 15$, $n = 800$.

This will give a safe margin in output,

Now, $E = e + i_a\ (r_a + r_m)$ . . . . . (5)

and, also $E = 695 + 0{\cdot}06 \times 695 = 736$. . . *From Table A.*

(Take one and a-half times the percentage, since the field resistance must be included.)

$$\mathbf{N}_a = \mathbf{B}_a'' \ 2\ rl\ 0{\cdot}85 \ (7) \ (\textit{see} \text{ Table B}).$$

$l = 15$, let $r = 2{\cdot}5$, and $\mathbf{B}_a'' = 110{,}000$

$$\therefore \mathbf{N}_a = 110{,}000 \times 5 \times 15 \times 0{\cdot}85 = 7{\cdot}0 \times 10^6.$$

Put this trial value of $\mathbf{N}_a$ in (8)

$$C_a = \frac{E60}{\mathbf{N}_a n 10^{-8}} = \frac{736 \times 60}{7{\cdot}0 \times 10^6 \times 800 \times 10^{-8}} = 780.$$

The circumference of armature = $\pi d = 47''$, deduct a space of $2''$ for the driving horns, leaving $45''$ for the winding. No. 11 S.W.G. will carry 17·875 amperes at a density of 1,800 amperes per square inch: it is $0{\cdot}116''$ in diameter when bare, and with 16 mils. of insulation = $0{\cdot}132''$. Therefore, with No. 11 wire the turns per layer would be $\frac{45}{0{\cdot}132} = 340$. Two layers would = 680 turns, *i.e.*, say 68 coils of 10 turns each. The resistance when cold will be about 0·37, and hot about 0·4 ohms.

Ampere-turns per coil = $10 \times 17{\cdot}875 = 179$ say

Permissible circumflux = D 1000 = 15,000 . . . . . (9)

Arranged circumflex $= \frac{i_a C_a}{2} = \frac{35{\cdot}75 \times 680}{2} = 12{,}200.$

Two layers of this wire give fewer turns than the value of C_a determined from (8), and *three* layers would give too many, besides increasing the air gap unduly, and raising the circumflux above the safe limits given by (9). This is a common case in practice; the remedy is to raise the speed, or to increase the armature induction; or to do both,

making $n = 800 \frac{780}{680} = 920$, say;

or, making $\mathbf{N}_a = 7{\cdot}0 \times 10^6 \frac{780}{680} = 8{\cdot}00 \times 10^6$;

or, by varying both n and $\mathbf{N}_a$.

To illustrate these points the latter method is chosen.

Since $\mathbf{B}_a''$ is already 110,000, in order to increase $\mathbf{N}_a$ it is necessary to make the cross section of the armature larger, alter the radial depth of core r from $2{\cdot}5''$ to, say, $2{\cdot}75''$. Therefore $2\ l\ r$ will = 82·5 sq. in., and the effective armature section will be $82{\cdot}5 \times 0{\cdot}85 = 70$ sq. in.

The new value of $\mathbf{N}_a$ is therefore

$$7{\cdot}0 \times 10^6 \times \frac{2{\cdot}75}{2{\cdot}5} = 7{\cdot}7 \times 10^6.$$

The speed must be raised to give the required conditions. Substitute these new values in (8), and solve for n

$$n = \frac{E\ 60}{C_a\ \mathbf{N}_a\ 10^{-8}} = \frac{736 \times 60}{680 \times 7{\cdot}7 \times 10^{-2}} = 835.$$

The bore of the poles must next be determined. Allowing for two layers of No. 11 S.W.G., suitable insulation, bands, and clearance of, say, 0·0937 (3/32″) of an inch all round the required bore is 15·75, and $\therefore \delta = 0{\cdot}375$. And let the angular width of the pole pieces be 120° at the edges, and 125° in the centre; *i.e.*, let the "horns" be curved in a direction parallel to

* All rights reserved.

Digitized by Google

the winding (*see* Fig. 13). This tends to destroy the abruptness of the magnetic flux, and to distribute it more gradually on the leading horns. The average width of the pole pieces, w, is 122·5°, or, say, 17″.

The length of the poles should be a little less than that of the armature core, say, in this case, 14·5. Therefore the area of each cavity is $17 \times 14{\cdot}5 = 247$ sq. in., and B''_g, the density in the gaps is found by dividing N_a by 247;

$$\text{or,} \quad \frac{7{\cdot}7 \times 10^6}{247} = 31{,}000.$$

This is a convenient density.

Next, to determine the field induction:

$$N_f = v\,N_a = 1{\cdot}42 \times 7{\cdot}7 \times 10^6 \quad . \quad . \quad . \quad (v = 1{\cdot}42)$$
$$= 10{\cdot}95 \times 10^6,$$

and half of this flux, $5{\cdot}475 \times 10^6$, must be supplied by each limb of the magnet.

Let the cores be wrought iron, and $B_f'' = 85{,}000$ say, and the area of each core $= \frac{5{\cdot}475 \times 10^6}{8{\cdot}5 \times 10^4} = 65$ sq. in. nearly.

Now the length of the pole pieces has been fixed at 14·5″, let the magnet cores be the same, then the width of each core is

$$\frac{65}{14{\cdot}5} = 4{\cdot}5''.$$

The dimensions of the machine are now sufficiently developed to enable a drawing to be made showing a cross section of the field and armature cores; let this be to, say, an inch and a-half scale, as in Fig. 13. The length of the magnetic paths can be estimated, and the field winding calculations made.

$m_f = 23''$; $m_{f1} = 16''$; $m_a = 7''$; $2\,l\,r = A_a = 70$; $A_f = 14{\cdot}5 \times 4{\cdot}5 = 65{\cdot}0$; $A_{f1} = 93$; $B_a'' = 110{,}000$; $B_f'' = 85{,}000$; $B_{f1}'' = 50{,}000$; and $B_g'' = 31{,}000$.

The path of the induction in the armature can only be averaged, since the density is not constant (*see* Fig. 14), which has been drawn specially to show the probable distribution of the lines of force. It is noticeable that the maximum induction only takes place in the areas bounded by the lines $a\,a_1$ and $b\,b_1$. Averaging the path to the density chosen, $B_a'' = 110{,}000$, it is seen that the mean distance between the pole tips is a fair approximation to the value of m_a. It is also interesting to mark how the direction of the lines is altered after leaving iron and entering air. This is to be expected from the very different permeabilities of the two media, a subject which is engaging the attention of experts.

The excitation per limb for full load is from (12)—

A.-T.'s for armature	$= m_a f(B''_a) =$	$7 \times$	$280 = 1{,}960$
,, cores	$= m_f f(B''_f) =$	$23 \times$	$77 = 1{,}771$
,, pole pieces	$= m_{f_1} f(B''_{f_1}) =$	$16 \times$	$130 = 2{,}080$
,, gap	$= 2\,\delta f(B''_g) = 0{\cdot}75 \times 9{,}750 =$		$7{,}300$
			$13{,}111$

The various "functions" for the determined values of the inductions are read direct from the proper curves in Plate I. Let the value of the ampere-turns be taken at 13,100.

To find the demagnetising turns: Let the maximum angular lead θ be 27°, *i.e.*, nearly to the tip of the leading "horn." Then, by (13), the compensating turns are

$$C.T._a = C_a \frac{\theta}{180}\, i_a\, v,$$
$$= 680\, \frac{27}{180} 35{\cdot}75 \times 1{\cdot}42,$$
$$= 5{,}150 \text{ nearly.}$$

(For value of "v" see Table D.)

And 2,575 ampere-turns must be added to the excitation of each limb, since (13) estimates the total demagnetising effect. Therefore the total excitation per limb is

$$A.T._a + C.T._a = 13{,}100 + 2{,}575 = 15{,}675.$$

With a series machine no calculation can be made for "open circuit," since it will not excite unless the main circuit be closed. If the dynamo be compound-wound, this calculation is necessary in order to determine the shunt winding; but for a simple shunt machine it is usually sufficient to determine the excitation at full load only.

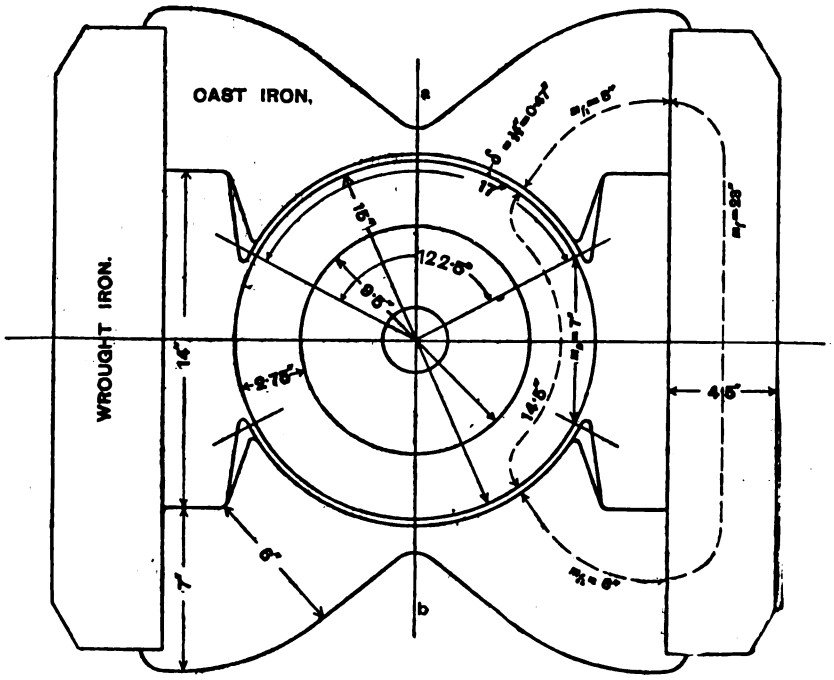

FIG. 13.—Cross Section of Dynamo, showing Method of Designing.

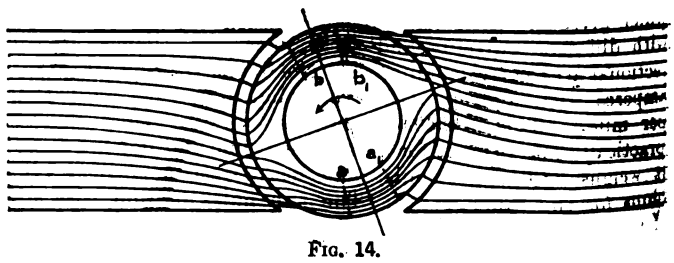

FIG. 14.

It now remains to find the gauge of wire for the field windings. This can be done in several ways, each depending on the result aimed at.

Digitized by Google

In a series machine* the current is fixed, and thus the gauge of wire is given by the heating effect, *see* § 9 (*a*); and the number of turns must be selected to give the proper excitation. In the design under consideration the convolutions required

$$= \frac{15675}{37{\cdot}75} = 440 \text{ per limb,}$$

and No. 5 B.W.G. will carry 38 amperes at a density of 1,000 per square inch of section; and this will give an ample margin. The resistance hot is

$$\frac{440 \times l_1 \times 0{\cdot}00064}{36} = \frac{440 \times 34 \times 0{\cdot}00064}{36} = 0{\cdot}258$$

where l_1 = length of a mean turn in inches, and 0·00064 = resistance of one yard of the wire.

The winding space is 14in. long, allowing 0·75in. for the two flanges of the "shape," and for insulation, there is left a net length of 13·25in. Now 4·25 turns of No. 5 B.W.G. (with 16 mils. insulation) will occupy 1in., and so the convolutions per layer will be 56. The turns per coil are 440; hence, 8 layers are required. The depth of the winding is approximately 2in.

The resistance of the two coils is about 0·516 ohms, and the total resistance of the dynamo 0·916 ohms. The pressure lost over this is—

$$35{\cdot}75 \times 0{\cdot}916 = 33 \text{ volts nearly.}$$

Now, in fixing the value of E, a fall of 6 per cent. or 41 volts, was allowed. The winding is thus within the required conditions. If desirable, the value for the total E.M.F. can now be readjusted and the calculations amended accordingly. Practically, however, it is sufficient to decrease the speed in the ratio of

$$\frac{695+33}{695+40} = \frac{728}{735} = 0{\cdot}99,$$

and speed = 835 × 0·99 = 830 revolutions per minute.

The design of the dynamo is now complete. That of the motor is substantially the same; but special care must be given to the driving horns and general details of the armature. The speed of the motor is proportional to the back E.M.F., *i.e.*, to

$$E_1 - i_a (r_a + r_m)$$

and the torque is:

$$\frac{\text{B.H.P.} \times 33{,}000}{2\pi n}, \text{ from (18),}$$

or

$$\frac{C_a i_a N_a}{852{\cdot}3 \times 10^6} \text{ from (16).}$$

Now, $E_1 = E - 104 = 632$ volts at motor terminals.

$i_a = 35{\cdot}75.$

$r_a = 0{\cdot}4.$

and let $r_m = 0.25$ (trial value with six layers on field cores, and 660 turns in all).

$C_a = 680.$

And n and N_a are the two unknown variables. If there be any particular speed, then n is also fixed. Let 720 be the required number of revolutions per minute, then $n = 720$, and the torque is given by (18)

$$\frac{25 \times 33{,}000}{2\pi\, 720} = 183 \text{ lb. ft.}$$

The peripheral pull on the armature at full working load is given by (19), and

$$= \frac{\text{B.H.P. } 33{,}000}{2\pi n} \cdot \frac{1}{g} = 294 \text{ pounds.}$$

(g = radius of armature in feet.)

The maximum stress at starting may easily be twice as great, or even more, so it is necessary to allow for a pull of, say, from 800 to 1000 pounds. Equating to (16), the value of the torque found from (18), and taking out N_a, the required value of the armature induction is found, thus—

$$N_a = \frac{183 \times 852{\cdot}3 \times 10^6}{680 \times 35{\cdot}75}$$

$$= 6{\cdot}45 \times 10^6,$$

and,

$$B_a'' = \frac{6{\cdot}45 \times 10^6}{82{\cdot}5} = 78{,}500,$$

$$B_g'' = \frac{6{\cdot}45 \times 10^6}{247} = 26{,}000,$$

$$N_f = 1{\cdot}4\ N_a = 9{\cdot}05 \times 10^6$$

$$B_f'' = \frac{4{\cdot}525 \times 10^6}{65} = 82{,}500,$$

$$B_{f_1}'' = \frac{4{\cdot}525 \times 10^6}{110} = 41{,}250.$$

The excitation is by (12):—

A.-T.'s for armature	$= m_a f(B_a'') =$	$7 \times 24{\cdot}5$	$= 172$
,, cores	$= m_f f(B_f'') =$	$23 \times 66{\cdot}5$	$= 1{,}530$
,, pole pieces	$= m_{f_1} f(B_{f_1}'') =$	16×63	$= 1{,}030$
,, gap	$= 2\delta f(B_g'') =$	$0{\cdot}75 \times 8150$	$= 6{,}120$
			8,852

The demagnetising turns* are practically the same as with the dynamo, and, therefore, the full excitation per limb is

$$\text{A.-T.'s} + \text{C.-T.'s} = 8{,}852 + 2{,}575 = 11{,}427.$$

Dividing this by the current, the required number of turns per coil is 320, or six layers as was assumed in the approximation.

This finishes the calculation for the motor. The figures have been estimated by means of a slide rule, and so are not always quite exact; but they illustrate the use of the equations, and show the general method of designing dynamos and motors. It is interesting to notice that the motor is rather large for the output, and that the inductions in the field cores and gap are consequently much less than those required in the dynamo. This can be obviated to some extent in practice, by reducing the section of the motor cores, making them, say 4in., instead of 4·5in., in depth. Such alterations will readily suggest themselves.

(*To be continued.*)

* If the field coils were in shunt, then the potential difference would be fixed, and the current and turns be variable, the efficiency increasing with the number of turns for a given value of the excitation. Now there is one gauge of wire, and one only, which will give a particular excitation, for the given section of core, at a fixed potential difference. This wire being used, the number of convolutions affects the efficiency and not the value of the excitation. Therefore, it is necessary to find the proper area of cross-section of wire, and usually as it is not a stock size the *next size larger* is chosen. This increases the number of ampere-turns; but an external resistance is easily put in series with the coils, and hence the potential difference can be adjusted for any required excitation. The method followed is to first find the length of a mean turn of the coil, say it $= l_1$ inches; then, the resistance of a mean turn

$$= \frac{e_1}{\text{A. Ts}},$$

where e_1 = the potential difference available; and the gauge of wire can be found by reference to a table of wire resistances.

* Probably the lead at full load will be from 5 deg. to 10 deg. less than that required with the dynamo. If this be so, the compensating turns will be correspondingly less.

EFFECTS PRODUCED BY USING AN INDUCTIONLESS SHUNT WITH A CHOKING COIL.

BY HUGH ERAT HARRISON, B.SC.

Some measurements were being made on the London Electric Supply Corporation's circuit by Mr. G. W. Partridge, for the purpose of which conductors were connected up, as shown in Fig. 1. The points X and Z were connected to the mains, so that the E.M.F. between them was constant, and may be taken as 100 volts. S is the coefficient of self-induction of the choking coil; the other symbols, denoting the current, resistance, and E.M.F. between the various points in the circuit, are shown in the diagram. Before the shunt was brought into use, that is, when $r_2 = \infty$, the E.M.F. between Y and Z was 96; but when the shunt was thrown in to lessen the effect of the choking coil, and slightly raise this E.M.F., it was found the value of e_2, contrary to intention, fell, and on

Digitized by Google

diminishing r_2, continued to fall to below 90, after which, on further reducing r_2, e_2 rose continuously, until, when $r_2 = 0$, and the choking coil was completely short-circuited, it became equal to E.

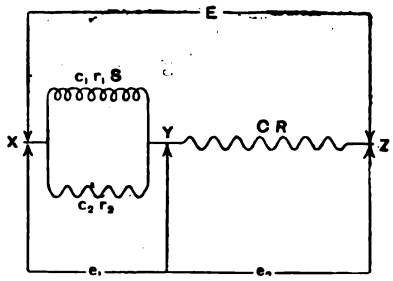

FIG. 1.

That a non-inductive placed in parallel with an inductive resistance may be made to reduce the voltage in an alternating circuit more than the inductive resistance alone, is shown by the more or less complicated equations for finding the currents in the branches of a mixed circuit, but graphical solutions of such problems are more easily followed by those unfamiliar with differential equations.

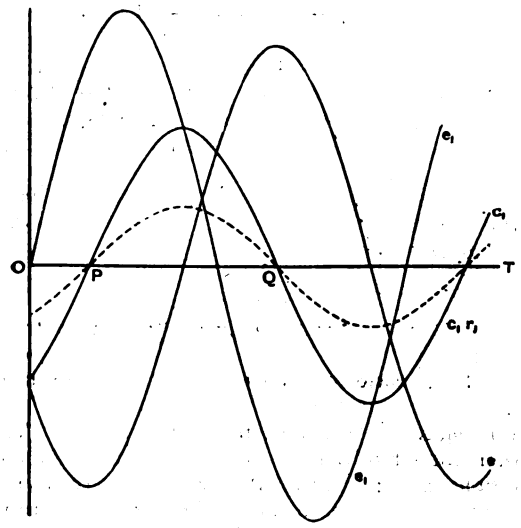

FIG. 2.

Lapse of time being measured along the horizontal line O T (Fig. 2), and the simultaneous values of other quantities in the vertical direction, let the curve e_1 represent the alternating E.M.F. at the ends of the choking coil; the dotted curve c_1 the current in this coil lagging behind e_1, and the curve ϵ the E.M.F. set up within the coil, due to self induction, lagging a quarter-phase behind c_1. If the ordinates of c_1 are multiplied by r_1, the resistance of the coil, a fourth curve is obtained showing the actual E.M.F. that drives the current through the coil, which is the sum of the E.M.F. e_1 applied to the ends of the coil and the E.M.F. ϵ set up within itself.*

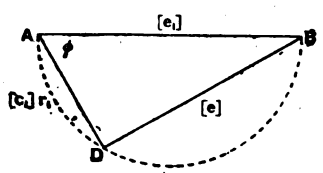

FIG. 3.

Let n = number of ∿ per second, $p = 2\pi n$, and let a symbol enclosed in square brackets, *e.g.* [E], denote the maximum value of the quantity in question.

The distance between the successive points where a simple sine curve ($y = \sin x$) cuts the horizontal axis is π, its greatest slope, which is at these points, is 1, and its maximum height also 1. The distance between the points P and Q on the curve c_1 is $1/2\,n$, its slope at P is therefore increased, above that of the simple sine curve, in the ratio $\pi : 1/2\,n$ or $2\pi n$ fold, but its height is $[c_1]$, hence the slope at P is $2\pi n\,[c_1] = p\,[c_1]$, and the maximum E.M.F. of self-induction $[\epsilon] = p\,[c_1]\,S$.

The resultant E.M.F. driving the current through the choking coil is, as already stated, composed of two E.M.F.'s, ϵ lagging a quarter-phase behind it and e_1 ahead of it in phase.

Lay off A B (Fig. 3), equal to $[e_1]$, describe on it a semicircle, and from B suppose B D drawn equal to $[\epsilon]$, then A D gives $[c_1]\,r_1$,

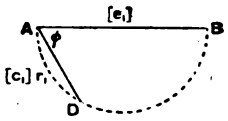

FIG. 4.

making, as it does, a right angle with B D; this shows the lag or difference of phase ϕ between e_1 and $c_1\,r_1$, or e_1 and c_1, that is, the difference of phase between the E.M.F. applied to the ends of the coil and the current which flows in it. Hence

$$\tan\phi = [\epsilon]/[c_1]\,r_1 = p\,S/r_1 \quad \because [\epsilon] = p\,[c_1]\,S$$
$$\phi = \tan^{-1} p\,S/r_1.$$

The lag of c_1 behind e_1 can therefore be easily calculated and, being independent of the current, remains the same, no matter how the currents in the branches are varied, a variation which does not affect p, S, or r_1.

It may be pointed out that Fig. 3 will also give the impedance, I, or apparent resistance of the coil:—

$$I = \frac{[e_1]}{[c_1]} = \frac{[e_1]r_1}{[c_1]r_1} = \frac{r_1}{\cos\phi} = r_1\sqrt{1+\tan^2\phi} = \sqrt{r_1^2 + p^2 S^2},$$

Being now able to find the relations between e_1 and c_1, a simple series of constructions can be drawn to give the relations between all the quantities involved in the circuit. The

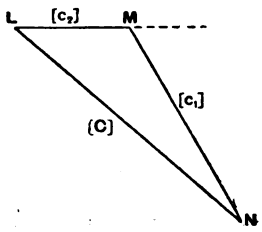

FIG. 5.

currents in the conductors which are inductionless are always in phase with the E.M.F.'s between their ends, and the simple relations $e_1 = c_2 r_2$, $e_2 = C R$, always hold for these instantaneous as for unvarying currents.

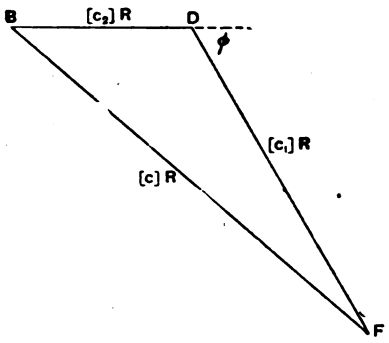

FIG. 6.

If E.M.F. or current be measured by ordinary instruments, the maximum instantaneous values will be $\sqrt{2}$ times those indicated.

In the following diagrams the same letters are used for corresponding points.

First calculate ϕ, then for any value of $[e_1]$ draw A B = $[e_1]$ (Fig. 4), and thus, as explained by Fig. 3, find $[c_1]\,r_1$.

The current C is at any instant equal to the sum of the simultaneous currents c_1 and c_2, though, as these latter are not

* *See* Paper by same Author in *The Electrician*, Vol. XXVIII., p. 223.

Digitized by Google

in the same phase, C is not equal to the algebraic sum of these currents as measured on ammeters, nor is $[C]$ equal to $[c_1]+[c_2]$, but the difference of phase between c_1 and c_2 is known to be ϕ; $[C]$ can therefore be drawn as follows. $[c_2]=[e_1]/r_2$; set off $LM=[c_2]$ (Fig. 5); $[c_1]$ is known, since $[c_1]r_1$ has been found by Fig. 4; draw $MN=[c_1]$ making the angle ϕ with L M produced, then $LN=[C]$ in both magnitude and phase. The quantity really wanted, however, is $[e_2]=[C]R$,

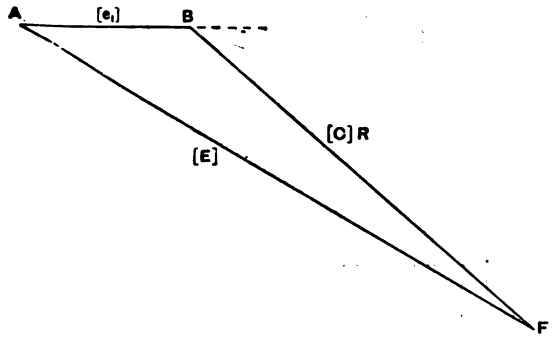

FIG. 7.

which could have been got at once by setting off $BD=[c_2]R$ (Fig. 6), $DF=[c_1]R$, making the angle ϕ with B D produced, when $BF=[C]R=[e_2]$.

Just as C is equal to the sum of the simultaneous values of c_1 and c_2, so is E equal to the sum of the simultaneous values of e_1 and e_2, though not in phase with either.

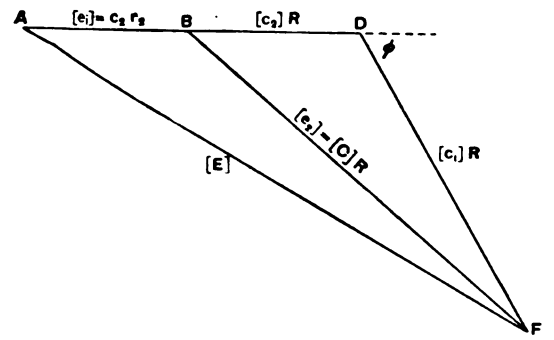

FIG. 8.

To draw $[E]$ (Fig. 7) set off $AB=[e_1]$, $BF=[C]R$, so that the angle B F makes with A B produced is equal to the angle D B F (Fig. 6), then A F gives $[E]$ in magnitude and phase.

The constructions in Figs. 4, 5, 6, and 7 have been shown separately in order that each step might be easily followed, but by piecing together Figs. 6 and 7, Fig. 8 is obtained, showing at a glance the relative values of $[e_1]$, $[e_2]$, $[E]$; the currents in

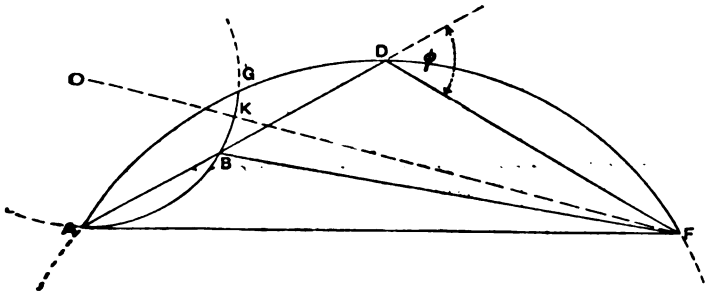

FIG. 9.

the various branches $[c_1]$, $[c_2]$, $[C]$ and their phases, the current in each case being found by dividing the lengths of D F, B D, and B F by the value of R.

In the experiment described at the commencement of the Paper, E, the E.M.F. between the mains, was kept constant, hence A F is constant. S, r_1 and p were constant, hence ϕ is constant, as was also R, but r_2 was changed from infinity down to zero. Since A F and ϕ are constant, D always lies on the arc of a circle passing through A and F. This arc is drawn in Fig. 9. It is not, however, so clear how the all-important point B moves.

From Fig. 4 $[e_1]=k\,[c_1]\,r_1$ where k is a constant.

But $\dfrac{AB}{DF}=\dfrac{[e_1]}{[c_1]R}=k\dfrac{[c_1]r_1}{[c_1]R}=k\dfrac{r_1}{R}$, a constant quantity.

The sum of the angles B A F and D F A is constant, so that when D F turns A B turns through an equal angle; since the ratio between them is constant and D traces out the arc of a circle, the locus of B is also the arc of a circle situated with respect to A B as the arc D F is to the chord D F. The construction of this circle is a matter of elementary geometry. Its centre is at O; it cuts the larger circle at A and G, the limits of the path described by B.

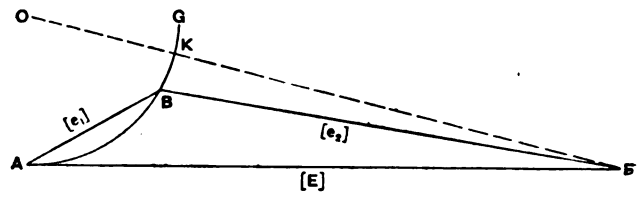

FIG. 10.

When B is at G, $BD=0$; there is no passage through the shunt, and the choking coil alone is in series with the resistance R. When B is at A, $AB=0$, that is, $[e_1]=0$, the choking coil is short-circuited, and the resistance, R, alone is across the mains.

Fig 10 is a reproduction of Fig. 9, omitting all the lines not required for the purpose in view, and, therefore, showing more clearly what happens when the shunt is brought into circuit and its resistance gradually diminished, until the choking coil is entirely cut out.

The E.M.F. between X and Y (Fig. 1) has its highest value when the choking coil is unshunted or $r_2=\infty$. As the point B (Fig. 10) moves towards A, the E.M.F. between Y and Z, Fig. 1, falls until B (Fig. 10) gets to the point K which lies on the line joining F to the centre of the arc G K B A, from thence onwards e_2 increases until the choking coil being short-circuited $[e_1]=0$ and $e_2=E$.

Briefly, the function of the choking coil is to protect or screen the resistance R from the full E.M.F. in the mains. This it does by producing at its ends a certain E.M.F. e_1, out of phase, however, with the main E.M.F. As current is shunted past the coil the value of e_1 falls, and its protecting power is correspondingly *lessened*, but while falling it gets more into phase with E in consequence of which its protecting power is *increased*. From G to K, Fig. 10, the increase of effect due to A B getting more and more into line with A F is greater than the loss of effect due to A B or e_1 getting smaller, so that the E.M.F. B F between the ends of the resistance R diminishes, but as r_2 is further lowered, that is when B has passed K, the reverse takes place, the increase of effect due to A B getting more and more into line with A F is less than the loss of effect due to e_1 getting smaller; B F thenceforward increases continually, until ultimately B F = A F, and the choking coil is completely short-circuited.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, June 2nd.

LONDON CHAMBER OF COMMERCE.

3 45 p.m. Meeting of the Electrical Trade Section

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Study of Fluid Motion by means of Coloured Bands," by Prof. Osborne Reynolds F.R.S.

MONDAY, June 5th.

ROYAL INSTITUTION.

5 p.m. General Monthly Meeting.

WEDNESDAY, June 7th.

ROYAL SOCIETY.

9 p.m. Annual Conversazione.

FRIDAY, June 9th.

PHYSICAL SOCIETY.

5 p.m. Papers to be read: (1) "A New Photometer," by A. P. Trotter; (2) "Notes on Photometry," by Prof. S. P. Thompson, F.R.S.; (3) "The Magnetic Field Near a Wire," by Prof. M. Minchin, M.A.

The Electrician.

(The Oldest Electrical Journal.)

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.

Editorial, Publishing, and Printing Offices:

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone No. 2714. Telegrams: "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*"

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November. Old Back Numbers and Volumes of* "THE ELECTRICIAN" *are frequently wanted, and offers will be made by the Publisher therefor.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0
Other Countries	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 4.30 p.m. Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.*

"THE ELECTRICIAN" SERIES *at present consists of—*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.
- VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free.
- VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post-free.

The same in German, price 8s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING (1893). By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. [*Nearly ready.*

The Publisher is able to supply a set of the Volumes of "THE ELECTRICIAN" complete except for three Nos. Price on application.

PHYSICS AND METAPHYSICS.

The greater part of the last two meetings of the Physical Society has been devoted to the reading and discussion of a Paper by Dr. OLIVER LODGE entitled "The Foundations of Dynamics." In this Paper, which will no doubt shortly be published elsewhere, the author deals with "The Nature of Axioms," "The First and Third Laws of Motion," "The Conservation of Energy and Universal Contact-Action," and other subjects, amongst which are the "Nature of Potential Energy," and the ever-to-be-discussed "Second Law of Thermodynamics." Appendices to this Paper deal with "The Objectivity of Energy and its Transmission." From one point of view it may be considered somewhat late in the day—or rather in the century—to deal with the foundations of so highly developed a structure as that of Dynamical or Physical Science. We may investigate the foundations, examine any weak places, and perhaps lay a footing for some new extensions, but a project for underpinning the whole fabric and for pulling out the old work and replacing it by new materials laid in a more modern fashion will find but few sympathisers. These foundations consist of so-called "axioms," "rational notions," "self-evident truths," and the like. It is possible that from time to time a little modification may be necessary, for in the history of science there is more than one striking example of collapse and of subsequent reconstruction, and though no widespread disaster can be conceived which could put Physical Science to confusion, it is well, perhaps, that a few cool-headed explorers should now and then leave their test-tubing and their spot-watching, and, descending below the pleasant

Digitized by Google

world of experimental science, grope and survey the foundations which lie among the murky regions of metaphysics. Systems of astronomy, of botany, of chemistry, and of geology, laboriously built, have been in some cases quickly razed, and in others have gradually fallen into ruin. In most of these there was but a halfpennyworth of experimental observation to an intolerable deal of theorising. The observations, such as they were, were for the most part sound, and the result of much patient work. Many are still useful, and even the misconstructed ones are instructive. The theorising was generally rash, and the generalisations which once seemed to be of fundamental importance hardly possess even interest to-day.

But here we must leave the metaphor. If these foundations consist of axioms, what is an axiom? The definition, "a proposition whose truth is so evident that no reasoning or demonstration can make it plainer," is a feeble one. It might be pleaded by a lazy student that the fourth proposition of EUCLID's first book, together with one or two others, are axioms, and if the evidence of a truth has anything in common with the intellectual effort of appreciating it, some of these propositions are more worthy of being called axioms than several of the so-called axioms of geometry or of dynamics. A better definition of an axiom, and one at least which does not seem to shirk the *onus probandi*, is "a concept based on experience." This does not make a vain attempt to treat an axiom as a ridiculously simple affair; on the contrary, it can only be rationally discussed by one who has had experience and whose mental powers are capable of apprehending a purely abstract notion. In this sense, then, the metaphor of foundations fails, for an axiom is the result, and not the starting point, of experience and thought. If not foundations, then, what are these knotty ideas and debatable laws and doctrines? They appear to be generalisations by which knowledge may by systematisation become science. So far from being postulates, they are the final inferences of reasoning. Viewed in this light, axioms become in the highest degree descriptive, and are proportionately valuable. Regarded as mere premises or initial ideas, axiomatic laws such as NEWTON's laws of motion, or definitions such as those of force, mass, or energy are likely to lead, if too closely discussed, into tangled controversy and intricate reasoning. Verbal definitions, said a speaker at the last meeting of the Physical Society, can only lead to verbal conclusions.

Verbal definitions are of this use, that having settled upon them, each may know what the other is talking about. An idea of "uniform motion in a right line" may be acquired by any school-boy, but it appears that if he is tempted to improve on this idea he will not only suddenly find himself out of his depth, but will to his great surprise discover that the profoundest thinkers well-nigh despair of defining exactly what is meant by these words. The fact, however remains, that except for the purpose of quibbling and prying into the limitations not of our knowledge, but of our vocabulary, the expression "uniform motion in a right line" conveys all that it need convey to him to whom they may be addressed. True, one man may be unable to define to the satisfaction of himself or of another what he means by "a right line," and somebody else who has trifled too much with philosophy may have so addled his brain that he cannot satisfy himself with a definition of "uniform motion." Verbal definitions truly lead to verbal conclusions, and we may add that verbal quibblings lead to verbal confusion. Our vocabulary is large enough to furnish names for the fundamental ideas of most sciences, and new terms can be coined from Greek if need be. We restrict the word "energy" to a definite meaning differing altogether from that in which ARISTOTLE used the Greek equivalent, and we have divested "force" from its many vague uses, and have restricted it to one well-defined idea. If anything is to be gained in the study of Physics by going behind the scenes into Metaphysics, let those who are competent to do so plainly tell us.

Alleys, some of them *culs de sac*, lead off from every path of science, but only the strong man can force his way through them and come out again on the highway having made real progress. How much time has been fruitlessly spent on abstract considerations of space? Is the Universe infinite? This was the question which Sir ROBERT BALL asked and sought to answer in the *Fortnightly Review* for last month. The dilemma of space, that it must either be infinite or there must be a boundary behind which there is an infinite unknown, Sir ROBERT BALL argued, no longer existed. The notion that one could travel on and on in a straight line for ever, and the idea that, if one went far enough, one would come against the "brick wall" of space, are equally unnecessary, and are alike based upon a fallacy. Who says that two parallel straight lines do not meet till produced to infinity? Who maintains that the three angles of a plane triangle are together equal to two right angles? Ah, but he cannot prove it, neither is it axiomatic. If we stand on the sea shore, we may draw two parallel lines in the sand, and say to ourselves that if they are produced they will either reach the edge of the world or else the world must be infinitely extensive; forgetting that Columbus could have told us that by following those parallel lines we should get back to the starting point in a finite time. So, standing upon the sea of space, and looking along what seems to be a straight line across it, we may really be looking along a gigantic curve, which, if followed, would bring us back to the origin in a finite distance. Space may be a closed curvation, a three-dimensional spherical "surface," as it were, possessing neither boundaries nor infinite extent.

Logic enables us to think without confusion, and in moderate doses is of great use to the physicist. To meddle further with abstract reasoning is likely to do him more harm than good. It is the fashion for students of the natural sciences, even while they are talking metaphysics, to say that metaphysics is rubbish; and it is the fashion for metaphysicians to say that there is no real physics but metaphysics. The diseased state of mind into which intelligent men may fall if they allow themselves to obscure plain ideas with philosophical considerations is well exemplified by the problem which DR. LODGE gives about the horse and cart. He says that he "constantly finds examination candidates, and even engineers, when catechised about a horse pulling a cart, though they may, some of them, politely admit that approximately the pull of the horse and the pull of the cart are equal (constituting the stress in the trace whose inertia we may agree to neglect), yet nevertheless assert that in reality the pull of the horse must be the least little bit bigger than the back pull of the trace, else the thing could not start." Unhappy "candidates and even engineers"! Unless such a difficulty were suggested externally, no natural mind could conjure it up. Would not the paradox, such as it is, be greatly increased by assuming the harness to be an epidermal extension of the horse, or by tying a loop in its tail dispense with the massless trace? The old Greek philosophers who had nothing better to do rejoiced in such puzzles. There was one about a fish; we do not remember the exact proposition. A fish was in a bowl of water. The fish could not move unless the water gave place before it. But the water could not move until the fish displaced it; how, then, could the fish ever move? The

Digitized by Google

problems of ACHILLES and the tortoise, or the modern version, of the minute-hand and the hour-hand of a watch, are really of more interest than these horse, cart, and fish dilemmas, for the summation of fractions, and the true presentation of the problem are instructive.

The intention of Dr. LODGE's Paper and discussion appears to be to examine the fundamental ideas, and to see whether they are resolvable into components, and to discuss whether one be more fundamental than another. The resolution of energy into two factors, as pointed out by Prof. S. P. THOMPSON in the adjourned discussion, is, indeed, a point of no little importance when the objectivity or identity of energy is under consideration, but to argue whether mass or force is the more fundamental idea does not seem to be of much utility. The more familiar, or apparently simple, idea claims the place, and as these attributes are matters of opinion, no definite conclusion is possible. Dr. OLIVER LODGE, we understand, prefers to take "force" as fundamental and "mass" only as an inference, as a useful secondary idea. He admits that "heat is a convenient term; there are reasons for using it." In these and similar preferences we cannot but think that he is in a small minority. Let us by all means clear our ideas about mass and force and time, but to tear to pieces such useful conceptions by desperate attempts at new and perfect definitions is like the inquisitive destruction of toys by a child. He is generally sorry in the end for the mess he has made.

REVIEWS.

Alternating Currents. By F. BEDELL, Ph.D., and A. C. CREHORE, Ph.D. (New York: W. J. Johnston and Co.)

According to the authors of this book, the recent advances in the applications of alternate currents have been so numerous and important that "there are now many interested in this field of work who desire to become conversant with the underlying principles of the subject, in order that they may become better equipped to undertake the vast engineering problems which are constantly arising." The hurried way in which the subject has advanced has caused the theory to be "developed this way and that, and added to here and there, so that it is necessary for one to stop and consider the basis from which certain conclusions are reached, and the logical sequence by which the results are attained." The authors, however, have made a mistake in attempting to supply this want by writing a book which is from first to last a purely mathematical work. Reference to experiment there is none, unless numerical examples in illustration of the formulæ can be accounted as such. It has been more than once pointed out that, unless a liberal interpretation is given to the symbols used in alternate-current mathematics, the formulæ arrived at do not represent experimental results. No indication is given in the book of methods, practical or otherwise, of determining those two or three quantities with which the whole book is concerned. No reference, indeed, is made to any kind of alternate-current measuring apparatus. The book is far more suitable for mathematicians who have heard about the existence of alternating currents, and desire to have them explained in a mathematical fashion, than it is for electricians wishing to gain precise ideas about the principles underlying their work.

The book consists of two parts, devoted respectively to the analytical and graphical methods of treating the subject. The first part is well illustrated by a number of curves drawn to represent special cases, the numerical details of which are given. These curves show very clearly the nature of the electrical actions going on. But the analytical portion betrays too great a tendency to desert electrical matters and wander into the regions of pure mathematics. Thus, when discussing on p. 42, the equation

$$e = \mathrm{R}\,i + \mathrm{L}\frac{d\,i}{d\,t},$$

the authors think it advisable to consider the condition of integrability of the general type of a differential equation of the first order, involving three variables, viz.,

$$\mathrm{P}\,d\,x + \mathrm{Q}\,d\,y + \mathrm{S}\,d\,z = 0;$$

and having, by means of a reference to Johnson's Differential Equations, obtained this condition in the form

$$\mathrm{P}\left(\frac{d\,\mathrm{Q}}{d\,z} - \frac{d\,\mathrm{S}}{d\,y}\right) + \mathrm{Q}\left(\frac{d\,\mathrm{S}}{d\,x} - \frac{d\,\mathrm{P}}{d\,z}\right) + \mathrm{S}\left(\frac{d\,\mathrm{P}}{d\,y} - \frac{d\,\mathrm{Q}}{d\,x}\right) = 0,$$

the writers proceed to show that the equation given above connecting the electromotive force e with the current i does *not* fulfil this condition, and that it therefore cannot be integrated without more data being known. The simplest consideration of the physical meaning of the problem would have rendered this result evident without resorting to mathematics at all; for the equation applies to *any* circuit, and the electromotive force e may vary in *any* manner. A long proof is given, in Chapter XI., of the fact that the heating effect of an alternating current may be greater while the current is flowing in the positive direction than while it flows negatively. This happens even when the area of the positive part of the curve is equal to that of the negative part, provided the shapes of the two portions differ from each other. Such currents no doubt do occur, in arc-lamp circuits perhaps, but they are rare, and hardly merit much attention. In any case, however, the suggestion, made by the authors, that the inequality of the heating effects of the positive and negative parts of the current "may afford an explanation for the fact that in many cases one carbon of an alternating-current arc lamp is consumed more rapidly than the other, depending upon the way it is connected up," is curiously erroneous. Whatever may be the law of variation of the alternating current, this certainly passes through both carbons of the lamp. If the positive portion of the current only passed through the upper carbon, and the negative portion only passed through the lower one, the author's suggestion would apply.

The book is very complete. It discusses fully the action of circuits containing resistance, self-induction, and capacity, the measurement of alternating-current power, and the propagation of currents along cables with capacity and self-induction distributed along them. It contains more than a hundred figures, all of which are new, many of them representing numerical examples, and a great many of them, especially in the latter, or graphical portion of the book, consisting of original constructions. In preparing these, a considerable amount of useful work has been done. The general get up of the book is excellent. It is, however, unfortunate that the character of the book is so theoretical. Nowhere do we find it stated that the self-induction of the circuits occurring in practice is, in most cases, *not* a constant, owing to the presence of iron, and consequent hysteresis. Many of the proofs given in the book are rendered unsatisfactory from this cause. The printing, as already stated, is good. Nevertheless, we think it a pity to use the letter D, as is done throughout the book, for the differential operator d/dt, as it is so liable to be confused for an ordinary symbol of quantity when occurring among a number of other letters of the same type. Another objectionable feature of the same kind is the use of the two letters Im to signify $\sqrt{\mathrm{R}^2 + \mathrm{L}^2\omega^2}$. A single symbol would be much better to prevent confusing Im with an ordinary product of two symbols. The suggestion is made to use the word "impediment," for circuits containing both self-induction and capacity, to represent the ratio of volts to amperes, *i.e.*,

$$\sqrt{\mathrm{R}^2 + \left(\frac{1}{\mathrm{C}\,\omega} - \mathrm{L}\,\omega\right)^2}$$

where R is the resistance, C the capacity, L the self-induction, and ω is the quantity, $2\,\pi$ times the frequency of the current. Even if condensers were used much in practice, which is far from the case, we should not think any fresh word necessary. The well-known word, "impedance," which Mr. Heaviside proposed for a circuit containing self-induction, can quite conveniently be used for circuits whose inductance is partially due to the presence of capacity. It is undesirable to multiply names till their need is more apparent.

SOME EXPERIMENTS ON THE ELECTROCHEMICAL EQUIVALENT OF ZINC.

BY JAMES ERSKINE MURRAY.

The experiments, of which I subjoin an account, were carried out at the suggestion and mainly under the direction of Mr. Thomas Gray, B.Sc., F.R.S.E., during the winter 1887-88, in the Physical Laboratory of Glasgow University. But as Mr. Gray left this country for the post which he now occupies in America before the results were collected and discussed, these are given entirely on my own responsibility.

As the electrochemical equivalent of copper had already been satisfactorily determined,* the simplest plan for the determination of that of zinc was to put several cells in which copper sulphate was electrolysed in the same circuit with some in which zinc sulphate was the electrolyte. In all these experiments there were six electrolytic cells, all in series, in the circuit; three with copper plates and solutions, and three with zinc. Thus the same amount of electricity passed through each cell in the series; and hence, from Faraday's law, determinations of the current, or of the duration of the experiment, were not required. The current was, however, observed in order to find the most suitable current density on the zinc plates. The electrochemical equivalent of copper being known, that of zinc was directly calculated from comparison of the amounts of copper and zinc deposited.

The method of experimenting was almost identical with that followed by T. Gray and A. W. Meikle in the electrolysis of copper compounds. The plates were polished with fine sand-paper. After polishing, the plates were dusted with a silk cloth, and then weighed. The copper plates having been prepared in the same way, all were placed in their respective cells and the current made. The duration of an experiment was usually about two hours, during which time the current was kept as nearly constant as possible.

Immediately on breaking the circuit the gain plates were removed from the cells and washed with pure water. They were then dried between folds of clean blotting paper, held before a bright fire for a short time, allowed to cool, and finally weighed.

The best results, as to appearance of deposit, at least, were got when the plates were used within an hour or less after polishing. Two loss plates and one gain plate were placed in each cell. On the gain plates the range of current density was from $\frac{1}{210}$th to $\frac{1}{30}$th of an ampere per square centimetre. On the smaller plates, with high-current density, the deposit becomes coarsely crystalline; on the larger it covers the plate only in streaks, leaving a considerable portion of the surface uncovered. In no case was a deposit which covered the plate uniformly obtained. But for this range of current density the deposit was always adherent. It was noticed that, after washing and drying, the parts of the polished surface on which there was no deposit seemed in many cases to be covered with a very thin and slightly brownish film.

The compound of zinc electrolysed was the sulphate. The stock solution, otherwise pure, had a large quantity of zinc carbonate in suspension, which, before the solution was used, was removed by careful filtration. The liquid was then diluted with pure water to a density of 1·4.

In order to determine the rate of gain or loss of weight due to the independent action of different solutions the following experiment was made:—Four zinc plates, numbers (1), (2), (3), (4) were used; (1) and (3) had a zinc electroplated surface; (2) and (4) were polished as for the experiments in electrolysis. After weighing, (1) and (4) were placed in a glass of the ordinary zinc sulphate solution which had already been used in several experiments, and therefore probably contained no free acid. (2) and (3) were placed in a glass containing about one-third of a pint of this same solution but to which one drop of concentrated sulphuric acid had been added. The plates were left in their respective solutions for twenty-three hours; and when taken out were washed, dried, and again weighed. By taking the sizes of the plates, and the differences in weight caused by immersion in the solutions into account, it was found that in the neutral solution the average gain per square centimetre per hour was $1{\cdot}3 \times 10^{-6}$ gramme; while in the acid solution the loss per square centimetre per hour was 5×10^{-6} gramme. In experiments K, L, M, a neutral solution was used; and in N, O, P, a solution slightly less acid than the above. In working out the numerical value of the electrochemical equivalent of zinc from each experiment, the equivalent of copper was taken as 0·0003287 gramme per ampere per second, which is the value given by Mr. T. Gray for a current density of $\frac{1}{30}$th ampere per square centimetre, and conditions of solutions such as existed in these experiments. The electrochemical equivalents of copper and zinc being in the same proportion as the deposits of copper and zinc, the latter equivalent is easily found by a simple proportion sum.

Looking at the table of results, it should be noted that in experiments K, L, M, the zinc sulphate solution must have been neutral or nearly so, while in N, O, P it was slightly acid. Hence, according to the experiments on the action of such solutions, described above, the real value of the numeric should lie between that given by experiments K, L, M, and that given by the experiments N, O, P. Now the average value of EZn, calculated from experiments K, L, M, is 0·0003391; that from experiments N, O, P, is 0·0003381. It is safe, therefore, to take the value 0·0003386 of a gramme per ampere per second, as an approximation to the true value.

A SIMPLE EXPERIMENT.

To obtain those luminous tube effects which created so much non-technical bewonderment last year, Mr. Nikola Tesla employed a whole armoury of appliances, including a special high-frequency alternator, oil transformers, and special magnetic interrupters. Mr. Nikola Tesla no sooner showd us how to do the thing in an elaborate manner than, as is invariably the case, everyone was showing everyone else how to obtain similiar effects by the most simple contrivances. The limit in this direction appears, however, to have been reached by M. P. Marsillac, who, in *La Lumière Electrique* for April 22nd, described the following rudimentary arrangement.

M. Marsillac employs three Lalande and Chaperon cells of the French telegraph pattern; a Ruhmkorff coil ten centimetres long by 3in. diameter, with an extra sensitive trembler break, and a thin-glass Geissler tube 10 or 15 centimetres long. With this toyshop apparatus, M. Marsillac is able to reproduce one of the most striking of Mr. Tesla's experiments. Shades we had all known increased the effective illumination obtainable from a given source of light, but when on that historic Thursday evening, at the Royal institution last year, Mr. Tesla applied a shade to one of his single-wire glow lamps, the candle-power of the lamp went up as well the candle-feet on the table below, we seemed to be getting dangerously close to perpetual motion in the shape of an indefinitely large amount of light derived from an indefi-

nitely small source of power. It is this pretty electrostatic experiment that M. Marsillac reproduces with the simple appliances above mentioned. He connects one terminal of the tube

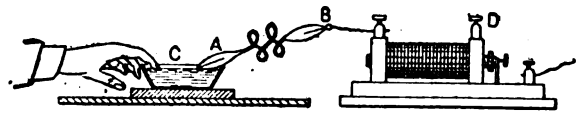

FIG. 1.

to one terminal of the coil, as shown (Fig. 1), having previously filed down the other tube wire, and dips the free end of the tube into a little china dish, C, resting on a sheet of ebonite, and containing either pure water, salt water, sulphate of copper, &c., &c. On dipping the finger into the liquid the tube commences to glow. Once started in this way the glow persists even if the finger is

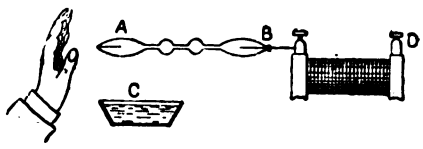

FIG. 2.

withdrawn from the liquid. On lifting the tube out of the liquid (Fig. 2) and bringing the hand up close to it the glow also continues.

THE HANOVER CENTRAL STATION.*

The Hanover central station, one of Messrs. Schuckert's design, was contracted for on May 2, 1890, and opened on March, 3, 1891. It offers several points of interest. The method of regulation and distribution by means of secondary cells has been adopted, and has been developed to such an extent that in this case the accumulators are of as much importance to the supply as the dynamos themselves. The station was designed to supply current to a load of some 50,000 8-c.p. lamps, and an enlargement took place last year. The boilers and engine house are of the usual type, and do not merit any particular description. The engines and dynamos, on the other hand, are more interesting. The former are triple expansion condensing engines, the three pistons working on a common shaft by means of three cranks at 120deg. from one another. This arrangement, shown in Fig. 1, is said (in combination with the flywheel action of the armature) to produce a very steady running combination. There are three engines, two of 300-400 H.P. and one of 500-600 H.P. Since the shaft rests on the bedplate of the engine, and the dynamos are direct-coupled, the floor of the engine-room is on two different levels, the dynamos being on the lower level. The regulation of the engine is said to be exceedingly good.

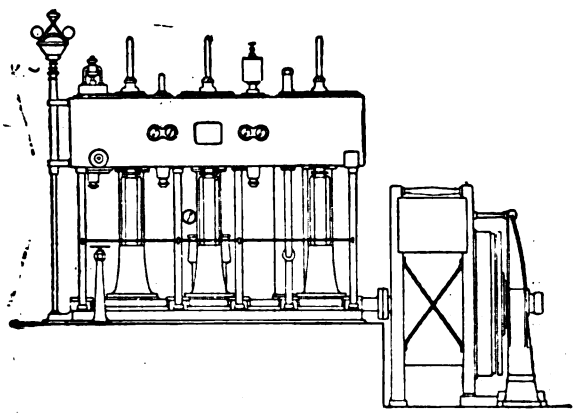

FIG. 1.—Hanover Central Station : Engine and Dynamo.

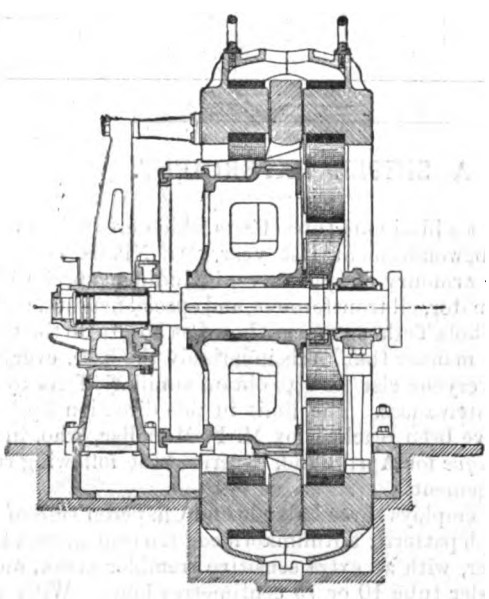

FIG. 2.—Hanover Central Station : Section of Schuckert Dynamo.

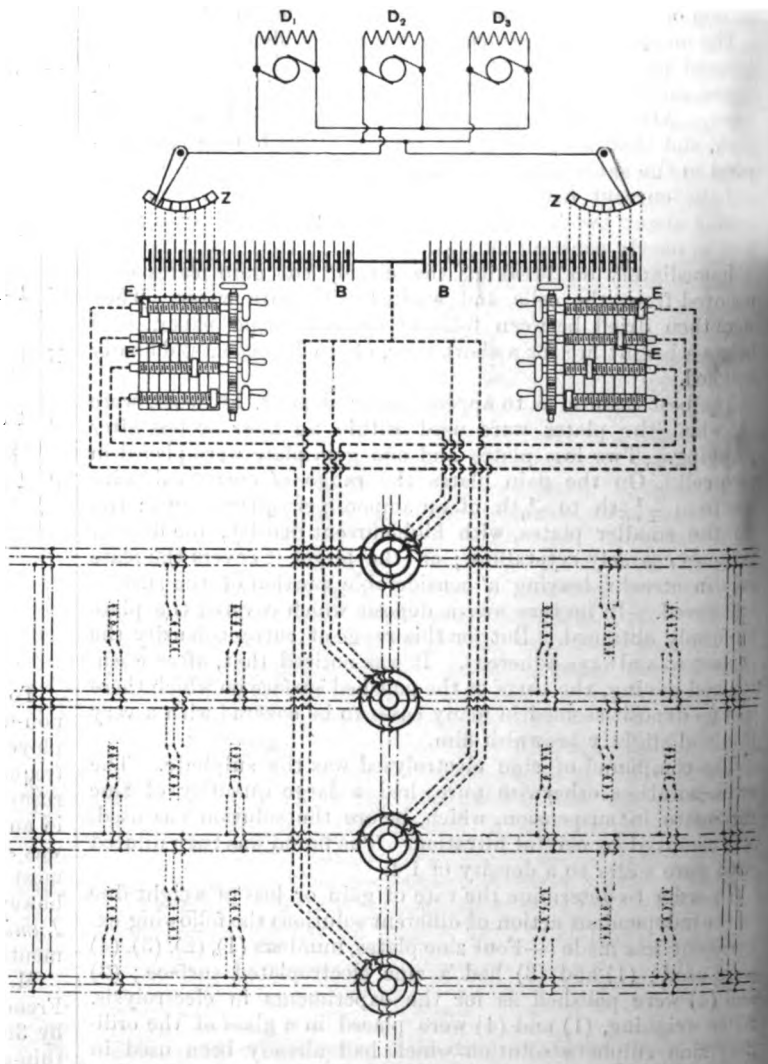

FIG. 3.—Hanover Central Station : Diagram of Distributing Arrangements.

The dynamos are ring armature machines of the multipolar type, and the current is collected by eight sets of brushes. The commutator has 840 segments, and is 6ft. 6in. in diameter. The output of each of the old machines is 275 kilowatts, and of the new one about 400 kilowatts. Fig. 2 gives a section of one of the machines.

The system of distribution is an improvement on that used at Barmen by the same firm, and is a method of charging the cells with the dynamos and discharging them into the feeders at the same time in the well-known manner; it is done here, however, on a large scale, and the charging and discharging switches are of ingenious form. An elaborate argument is entered upon to show the advantages of being able to separately regulate the pressure on individual feeders, so as to allow for different drops in different lengths of conductor. The diagram (Fig. 3) shows the arrangements:—D_1, D_2, D_3 are three dynamos in parallel; Z Z are the charging switches; B B the accumulators. The feeders are coupled to the batteries, a three-wire system being used. The feeder connections are, as shown, mounted on spindles, and are capable of independent movement, as well as combined motion, to take up variations of pressure due to differences in condition of cells. The form of the discharging switches is the most interesting point in this station. It is obviously necessary to use two contacts with a resistance between, in order to avoid short-circuiting the cells when moving from one contact to another, and with very large currents this resistance becomes too large to move about with the contact-maker. Again, since the pressure of the contacts must be very great to ensure absence of resistance and of heating, the insulation between the contacts gets rapidly worn away. These two objections have been met by the arrangement shown in Fig. 4, in which z_1, z_2, z_3 . . . are the cells, connected to the contacts c_1 c_2. . . . These contacts form, with the metal-piece a_1 a_2 . . . a metallic bed C_1 for the slider b_1, and similarly on the other side c_1 c_{11} . . . and a_1 a_{11} . . . form a bed C_2 for the slider b_2. These two sliders are mounted on a common block T, which can be moved up and down by means of the screw spindle *f*. In parallel with the metallic beds formed by a_1 . . . c_1 . . . are strips S_1 S_2, with which the sliders always make contact. Between S_1 and S_2 is the resistance *w*, which prevents a short circuit of the cell. By the double arrangement shown in Fig. 5, a_1 a_2 . . . may be part of S_1 S_2 without producing a short circuit. The circuit is as follows in the position drawn:—The current starts from the cell z_6, gets to to contact c_6, through the slides b_1 to S_1, through *l* to *w* the resistance, thence to S_2, and through the ammeter to the feeder. If the contact is across the line *x y*, the current goes from cell z_6 to C_{11}, thence through the slides to S_2 and to the feeder, the resistance being then cut out. In the intermediate position *u v*, the resistance is coupled across one cell, but this is only temporary, and no short circuits are possible. These switches are in use in Hanover in sets of six, one of which is used as charging switch.

The accumulators are of Tudor type, and have a capacity of 2,640 ampere hours, the charging current being 330 amperes; the contract efficiency is 70 per cent., but the very careful tests made show an average efficiency for the year of 80 per cent. The ventilation of the accumulator-house is performed by the draught of the chimney-shaft by means of suitably disposed channels.

The feeders into which these switches supply current are nine in number; three have a drop of 6-8 volts and six a drop of 12-15 volts. These feeders are large enough to supply 28,000 lamps at one time. The cable network is lead-covered, with sheathing of galvanised iron tape. The feeders, on the other hand, are laid, for mechanical protection, in channels of U iron, with flat cover. An extensive system of statistics is one of the features of the management of this station, and to this system and its results we may refer at some future date.

The illustrations (Figs. 5 and 6) show two views of the dynamo and engine room, and give some idea of the large scale on which the station has been designed.

ON THE PREVENTION AND CONTROL OF SPARKING; CONTINUOUS-CURRENT DYNAMOS WITHOUT WINDING ON THE FIELD-MAGNETS, AND CONSTANT-PRESSURE DYNAMOS WITHOUT SERIES WINDING.*

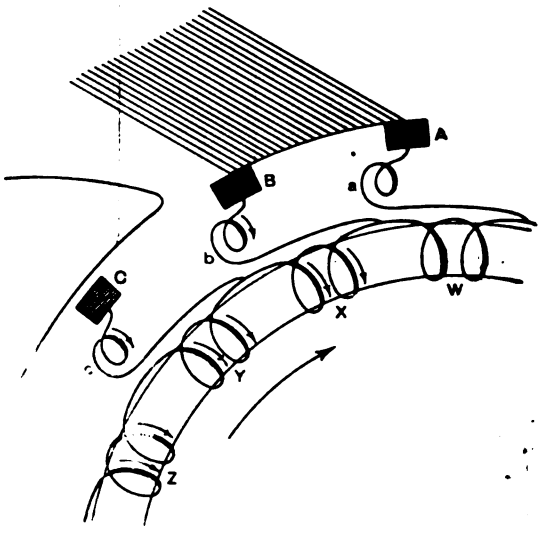
BY W. B. SAYERS.

DISCUSSION.

Speakers who have returned their proofs revised have asterisks placed against their names:—

THURSDAY, MAY 11TH.

*Prof. SILVANUS THOMPSON said he felt he was only expressing the sentiments of the whole of the assembled members when he congratulated Mr. Sayers upon his Paper and upon the information he had put before them. He had once seen in a ring-wound machine, an exaggerated case, in fact, of that to which Mr. Sayers referred, a machine with wide driving-pegs. It was a dynamo built in Paris by an engineer who wished to make the manufacture more simple by winding rings so as to get over the shuttling. He proposed to build the ring in two parts, winding each one separately and then screwing the two together by bolts. In evolving that mechanically there were two wide seams. The consequence was that he designed the commutator to match; it had 20 parts in one side and 20 parts in the other, with wide angular spacings to match the coils. The machine sparked most abominably. He then took off the commutator which had its segments spaced out, and put on an ordinary commutator with 40 equal pieces, and though there was still some sparking, there was less sparking than with the commutator specially designed to fit the segments of the armature. With respect to the point raised near the end of the Paper about the narrow air-space, of course all who took any interest in the details of machines were anxious to see armatures that should be more mechanical than those that had gone before, and when Mr. Swinburne first brought out those armatures with tunnels and Mr. Brown began to build them in Switzerland, they felt that the end of all things had been arrived at But somehow or other the end of all things had not come. Those armatures undoubtedly had advantages, but they still possessed the disadvantage of sparking badly. The magnificent machines designed for aluminium reduction at Neuhausen by Mr. Brown had to be sent back and the core discs turned down and the winding put outside, as in the ancient winding of Gramme rings, before they would consent to work without sparking. Mr. Sayers now showed what was the legitimate way of returning to that form of winding. If Mr. Sayers would pardon him, he would draw a diagram which would illustrate the winding in a way which would be clear to everybody. He would represent the successive coils of the armature by the usual symbol for cells; the "commutator" cells being not in the main closed circuit of the ring, but being each on open circuit until called upon to exercise their function of creating a sufficient electromotive force to balance the self-induction of the coils which are to be reversed in passing under the brush. In the accompanying figure the symbols for cells have been replaced by coils.



W, X, Y, Z, Sections of Armature Winding. *a*, *b*, *c*, Commutator Coils to furnish the E.M.F. necessary for Sparkless Reversal. A, B, C, Bars of Commutator. The Arrows represent E.M.F.'s, not Currents. The Current in W, which in passing under the brush has to be reversed; and this is effected by the E.M.F. of the coil *b*, which is still actively cutting the Magnetic Lines under the Pole, hence can overcome the Self-Induced E.M.F.'s of the Current in W.

*Mr. SWINBURNE said it was not too much to say that in a few years they would look back to this Paper as giving them the first hints, or the first description, of the greatest advance that had been made in the practical design of direct-current dynamos during the last ten years. He thought the more they looked into the method, and the more they looked into the developments of it, the more they would see the importance of what Mr. Sayers had not given them. He had given them a great deal, but there was more to follow. Mr. Sayers had introduced a new state of things. He (Mr. Swinburne) did not exactly know what the output of a dynamo was limited by now, unless it was by the ampere-turns they could get on the armature without over-heating it, and the difficulty which arose from hysteresis when they used very high inductions. He did not think Mr. Sayers had laid enough stress upon the importance of the smallness of the connections. A drawing of a machine such as Mr. Sayers had put before them, or such an ingenious diagram as Dr. Thompson's, looked as if it would be complicated when put into practice. But it must be remembered that those wires with the little auxiliary coils in them had only to carry a current for a very short time. That was a very important practical matter in the design of those machines. As regards the spaced commutator, he did not want to be critical where they ought to be entirely congratulatory, but he could not help thinking that Mr. Sayers was wrong theoretically about his dummy commutator. They had gone into the matter at Messrs. Crompton's some time ago, and came to the conclusion that it would not do. It seemed to him that the days of smooth armatures were over. The only reason why they had not had hole-wound armatures for a long time was the difficulty of sparking. When he first advocated hole-wound armatures he was quite aware of the difficulty of sparking, and proposed various forms of reversing pole-pieces to get over the difficulty. They had discussed the matter at Messrs. Crompton's, and although they had never made one, they had come to the conclusion that they would no doubt work, but were not good enough to make commercially. He did not think engineers generally recognised the enormous advantage of hole-winding. Not only did they get a mechanical machine, an armature they could take out and roll about the floor without hurting it, but

* Paper read before the Institution of Electrical Engineers, May 11th.

Digitized by Google

they got rid of the Foucault currents; and above all, when working with a hole-wound armature, they had no mechanical forces on the armature wire. The whole of the mechanical force came on the iron, and that was a matter of very great importance when they were dealing with insulation. They had no longer to get their torque communicated through cotton, shellac, and messes of that sort. He would ask them to read the last sentence of Mr. Sayer's Paper again, and to believe it.

*Mr. HOUSMAN said that some eighteen months or so ago he made a number of experiments at the works of Messrs. Willans and Robinson, which to a great extent bore out the conclusion that the average current in the commutated section might be extremely large in some cases. There was a point in connection with the commutation which was too often lost sight of, and that was the extreme importance of the surface resistance between the surface of the brush and the surface of the commutator. If the brushes were not placed in the proper position they had all the current crowded up into the front part of the brush, and there was a very considerable fall of potential at the tip, while at the heel there was no current, and consequently no fall of potential, and there was an E.M.F. round the circuit tending to help the reversal of the current. In the case of ordinary copper brushes the surface resistance was about the 1/400th of an ohm in a square inch; in the case of carbon brushes it was three or four times greater so far as he could measure. He found that, with the ordinary working full load of a dynamo and copper brushes, they might have a fall of potential of 0·3 or 0·4 volt between the brush and the commutator, and by shifting the brush forward and backward, in advance of and behind the best position they might have a difference of potential between segments under the brush of about half a volt or so in some cases, and that half-volt represented a reversing E.M.F., which had in a very much smaller degree something the same effect as Mr. Sayers's invention. The same thing might be produced to almost any extent by having the connections from the armature windings to the commutator made of high resistance. In the case of carbon brushes, he thought one of the principal benefits of them was that if the current was crowded up into the tip it did not stick to the commutator in the way that copper did if overloaded. It was often to be noticed that if a copper brush was overloaded the commutator immediately began to get rough, which he thought was due to the fusion of the point of the brush owing to the current being crowded up to the tip.

*Mr. W. M. MORDEY said he had not fully grasped the Paper yet, but he was glad that Mr. Swinburne had said what he was going to say, that it was of great importance, and that came very well from Mr. Swinburne, who had done, perhaps, more than anybody to lead up to the results that Mr. Sayers had obtained. This was one of the most pregnant and suggestive Papers on direct-current dynamos that they had had since the two Hopkinsons' Paper in 1886, and he was quite sure that the last words of the Paper were justified; Mr. Sayers had touched on the border of a new field of design, and they would see a great deal done in that direction. No doubt the result that he had arrived at could be traced back step by step. He thought it was nearly always the case that, when any real advance took place, everybody said it was a very simple thing and wondered it had not been thought of before. That was the kind of thought many of them had had that night. One must condole cordially with the writers of columns of mathematics on dynamos who had never arrived at any such practical result. Yet he thought it might, perhaps, be possible to go a little too far in following out this direction. He wanted to get information upon that point; he did not quite see the necessity of having all the excitation on the armature. In some ways it was the best place to have the excitation, but in others the worst. It was the place where they could least spare space; they could not work with a nice low-current density there as they could in the field. There, in the machine before them, for example, they had the field coil giving the initial magnetisation. He should like to know what the difference in the current density was in the armature considered as an exciting coil and in the field considered as an exciting coil, because he thought it would show how much more economical a certain portion of the excitation would be as regards energy if placed on the field-magnet in the ordinary way. It had been asked what the limit was going to be. He supposed Mr. Sayers would say simply the heating. If a machine were self-regulating and sparkless, with no drag on the conductors, he thought there was no limit except heating. Certainly the efficiency would not suffer. Was it not the fact that with high-pressure direct-current machines, hole-wound, or tunnel-wound armatures were rather difficult to wind? The machines that had been wound in Switzerland had all been low-pressure machines, and there was nothing to do but put a solid bar of copper through the holes and insulate them. This was an enormous advantage, but he was not at all sure that it would be found possible in small machines, at any rate for rather high pressures, to wind them through holes in that way.

*Mr. S. F. WALKER said he was about to take the unthankful office of throwing cold water on the Paper from the practical manufacturer's point of view. Before doing that, however, he would call attention to the great inconvenience to members of not having proofs of the Paper. Above all others, that was a Paper they ought to have had weeks before. Dealing with the Paper, he said he found fault with the channels and with the low clearance from the practical point of view. It was very difficult to insulate the wires properly when they were in a channel. He found fault most strongly with the small clearance. He should be surprised if Mr. Sayers had not found the armature touching a great many times. Good fitting, of course, would do a great deal, but they had to consider not only the fitting but the hands the machine had to go into. They had to consider that the spindles would bend unless they were very stiff, and other problems, and to a certainty they would get the armature out a little bit, and it would be running on the poles from time to time, and do more harm than good. All these devices for reducing the sparking and increasing the efficiency—were they worth the candle? When they got 1 or 2 per cent. efficiency, was it real efficiency? Was not the real efficiency what it cost to maintain, that was, the interest on its first cost, *plus* the cost of coal, and so on? It was an old engineering principle that when you got beyond a certain point every 1 per cent. cost more than it was worth. Engineers welcomed Papers of this kind and improvements of this nature, because, though they were rarely permanently successful, they advanced the standard at which real efficiency began.

THURSDAY, MAY 25TH.

*Prof. W. E. AYRTON said Mr. Sayers's Paper interested him very much, because it revived an old notion which Prof. Perry and himself put forward some years ago of using the armature field of a machine to help the field. Mr. Mordey, in the remarks he made, raised a doubt as to whether a certain amount of power for magnetising could be more economically employed in the windings of the armature than in the windings round the field-magnet. That, he thought, was not the proper way to look at the matter. It was not a question of whether it was more economical to produce a field by directly exciting the armature than by directly exciting the field-magnet. It was whether it was more economical to produce a field F + A by exciting the magnet, and a field − A by means of the armature, which was what was usually done, or simply to produce a forward field F by the armature. There could be no doubt as to the answer. It was more economical to produce the resultant field F by one magnetisation than by two opposing magnetisations F + A and − A. He (Prof. Ayrton) made tests ten or eleven years ago in Paris by measuring the efficiency and power of a motor with various leads. The more the lead was forward the better, as regards efficiency and power. In May, 1883, he showed at a lecture at the London Institution that, with a forward lead of the motor, it was not necessary to excite the field-magnet at all. A little later on, Dr. Hopkinson gave a Paper at the Royal Society on an analogous experiment, namely, that with a back lead a dynamo could be made to excite itself. But the orthodox makers of dynamos, perhaps not unnaturally, objected to this arrangement. How did Mr. Sayers look at the matter? By his device Mr. Sayers had succeeded in commutating his coil, not where it was usually commutated, but where it was best to commutate it. He had annihilated the sparks by an auxiliary device. The only difficulty in the arrangement was that whilst it was extremely compact, and, he doubted not, extremely satisfactory in its operation, it had the disadvantage that part of the main armature was wound with wire which was not operative in producing the main external electromotive. They had to have a number of auxiliary coils merely for the purpose of neutralising the spark and reversing the current. There were other plans which had been thought of for producing the same result. One plan, of course, was to have an auxiliary electro-magnet, or they could shape the field-magnet in a particular way at the place where they wanted to commutate. The worst plan of all, he thought, was the ordinary plan of commutating in the wrong place, simply because at that place there happened to be an electromotive force naturally introduced which would reverse the current. There was a plan which Prof. Perry and he discussed some years ago which might be worth mentioning. It was to introduce a completely external electromotive force by using two very narrow brushes close together to form the main brush, and a resistance inserted which could be adjusted; this electromotive force being produced by an accumulator or other convenient means. The auxiliary resistance and electromotive force were made sufficiently large, so that the current set up by the accumulator was not much larger when the two parts of the double brush touched one piece of the commutator than when they touched two. He thought Mr. Sayers was very much to be congratulated upon having revived what he ventured to think was the right principle in making a machine, and on having introduced a very ingenious contrivance to enable that right principle to be utilised without the destructive sparking which had always hitherto accompanied its adoption.

*Mr. ALBION T. SNELL wished to add his congratulations to those already given to Mr. Sayers for the neat solution he had given of a very interesting problem. The problem was, of course, an old one; he himself, as many as nine years ago, working with Mr. Swinburne, tried the plan Prof. Ayrton had put on the board, but it was not successful, owing to the diameter of commutation not being fixed. He was sorry Mr. Sayers had hitherto only applied his device to Pacinotti armatures, for he was under the impression there were considerable mechanical difficulties in applying it to smooth-cored armatures. He had tried toothed-core armatures, and after an extensive experience had gone back to the smooth core. He thought Mr. Sayers would have to do so too. There were two objections which struck him in connection with this application, and the first was the question of heating. At the present moment the limits to the output of a large dynamo were two. The first was sparking and the second heating. His experience, at any rate, had been that the output of a large armature was practically limited by the heating. The heating effect in the commutator coils was small, but he was afraid they were putting their compound coils in the wrong place. If they put them on the field-magnets they might have to use more wire and expend more energy, but the heat expended there could be readily controlled, whereas if the armature were already overheated it was not easy to do so. The largest armature Mr. Sayers had built so far appeared to be a 40-unit one. It was exhibited downstairs. He had roughly calculated the output by slide-rule, and estimated it to give something like 35,000 watts. If the stated output were correct, the objections which he raised did not seem to have much weight. There was one application of Mr. Sayers's principle which struck him at once, and that was its application to motors. The problem of motors, particularly series wound for traction work, had been complicated very much by questions of weight, and although in stationary machines weight could be neglected, on a tramcar it could not, and if they could lessen the weight of a machine by 15 or 20 per cent. by means of this device—and it seemed quite possible—a very material advance was marked in connection with motor design.

Digitized by Google

He would also point out that the device seemed to be chiefly applicable to series-wound machines, for in that case there was a possibility of entirely doing away with the excitation, but in connection with compound-wound machines they could only, at the best, hope to do away with series coils. From a conversation he had had with Mr. Sayers he gathered that so far as he had experimented with compound machines, he (Mr. Sayers) got a straight line, whereas in practice, what they wanted was not a straight line but a slightly ascending characteristic. So it appeared to him (Mr. Snell) unless the number of commutator coils were increased, they would still have to use series turns on the field-magnets, and the question was whether by using turns on both armatures and field they would gain much. Mr. Sayers's device undoubtedly marked a considerable improvement in the design of direct-current motors and dynamos, and he could not help thinking that manufacturers would not be very pleased to see it introduced, for it must have the effect of depreciating old stock.

Prof. GEORGE FORBES said it might be worth while mentioning, in connection with the introduction of secondary coils to overcome sparking that he had lately seen a dynamo in which that device was employed, but to get over a somewhat different difficulty. It was the device of one of the most ingenious of the American electricians, Mr. Eickemeyer, who made use of it to stop the sparking at the brushes of a direct-current series-wound motor, with laminated field when working from an alternating circuit, especially at the moment of starting.

Mr. ALEXANDER SIEMENS was astonished at the title of the Paper, because he thought sparking at the brushes was ancient history, and that modern dynamos did not spark. This device introduced complications which, from a manufacturer's point of view, were very objectionable. He spoke principally, of course, about the drum armatures, with which he was most acquainted. The object which a manufacturer must have in view was that he should give a good machine, which would produce a given output at the least cost. He could not go in for fancy work, and this extra winding which was to be put on the armature was certainly taking up useful space. If they were to adopt this device it should be clearly shown that it was cheaper to use it than to adhere to their ordinary construction. Several speakers had spoken of the sparks as great enemies, and all that sort of thing, but he wished to emphasise the fact that it was not nowadays at all difficult to make dynamos which would run sparklessly under any load and without any change of the position of the brushes. It was just the same with motors. It was not necessary for motors to spark, so long as they were not absolutely overloaded, and he did not see the use of such an application at all. It might do all Mr. Sayers said. He had certainly done good work in making the experiment, and showing what could be done in that way; but he entirely doubted the utility of the device from the manufacturer's point of view.

Mr. CHAMEN said he had seen the machine described in the Paper. It was wound to act entirely as a regulator, and was constructed to give about 13 volts when running with a current of about 40 amperes, or something like that. It was driven by a separate motor, and used in series with the main dynamo, or in series with the feeder, which carried current for a large number of lights to a considerable distance. It therefore acted as an ordinary series dynamo would, though, perhaps, considerably better, and gave a necessary increase in the voltage of the generating station, so as to make the voltage throughout the run exactly constant. It worked perfectly, without any sign of sparking. It was not working at full load when he saw it, only at about 30 amperes, but it was quite evident that it would work without sparking.

*Mr. MORDEY did not think the real point of Mr. Sayers's Paper had been grasped. Mr. Sayers enabled them to approximate a direct-current dynamo to a transformer. The excitation of a transformer required very little energy indeed; they were able in a transformer to do without any air space, and air space cost money, because they must supply energy to force the flux through it. It seemed to him that Mr. Sayers's Paper enabled them to get a very small air space, a mere mechanical clearance, that reduced the ampere-turns from thousands to hundreds. The ampere-turns on the armature must be there anyhow. If they could be used for the excitation of the whole machine, so much the better. He quite agreed with Mr. Siemens that modern direct-current machines ran sparklessly, but at what a cost! Look at a good modern two-pole or four-pole dynamo—at the amount of copper on it—at the many thousand ampere-turns necessary to get the magnetisation of the armature, at the magnetic field, and at the necessarily inefficient way in which they must apply the copper on the fields, the large quantity of it outside, and practically useless, mere end connections! It seemed to him that the real point was that they got rid of that great air space without losing the great advantage of non-sparking, and got rid of the necessity of putting a large amount of copper on the field, and paying a lot of money for that copper.

*Mr. CROMPTON said he should like, as a fellow manufacturer of dynamos, to corroborate what Mr. Siemens had said, without wishing in any way to dishearten Mr. Sayers in carrying on his most interesting experiments, which, no doubt, would be of very great value to them in the future. He wished to point out to him that Mr. Siemens was right in trying to keep before him the fact that the problem was solely one of expense. The dynamo machine had already arrived at sufficient perfection as regards the user, but it cost money to make, and if Mr. Sayer's improvements really had the effect of reducing the material and labour required in producing the dynamo or motor of a certain output, then he had achieved a great step in advance; but it was on that one point—and it was the sole point—on which they would ask him to throw light. Mr. Sayers was working at a problem which had been before dynamo makers for the last six or seven years, that of reducing the air space. The difficulty that had ruined that idea in the hands of everyone who had undertaken it, was the sparking—and when he mentioned the names of Swinburne, Brown, Ganz, and others, all of whom had made sunk windings on the armature, and all of whom had more or less failed—Mr. Sayers would see that the problem was one that had engaged their earnest attention, and if by his invention, and without extra expense, he did enable them to reduce air space, he had, indeed, made a great advance.

*Mr. SWINBURNE said it must not be taken for granted that this form of winding could only be used with hole winding. He was not at all sure about that. If a smooth core was used, there was, of course, a large air space; if there was a large air space it took less electromotive force to cause a reversal in the section; and, at the first blush, it seemed that they ought to be able to succeed almost as well with smooth as with hole-wound armatures. Of course, if they had a smooth-wound armature there was considerable difficulty, as the commutator connections all came so close together that it was difficult to have one connector out of the field while the other was in the field. He would like to hear how far it was possible, by lessening the number of commutator connections, to get over that difficulty. He did not know whether increasing the number of turns per section would increase the electromotive force available for reversing quickly enough. He hoped Mr. Sayers had worked it out carefully, and would tell them the result. Prof. Forbes had referred to the difficulty of making a series alternating motor of a simple series-wound direct-current machine with laminated fields. There were two main difficulties: The first was due to the self-induction of the machine. That induction could be overcome, to a certain extent, by condensers. But that was a serious objection; people did not want to put condensers in their houses with motors. The other difficulty had not been very fully realised. That was the objection of the sparking at the commutators. He thought that might be got over by winding the armature double, as was sometimes done for large currents; in that way they would have two complete circuits round the armature. If their brushes were only the breadth of one section, they never short-circuited a section, they simply passed from one armature circuit to the other. At first it might sound as if he were proposing to only half utilise the armature, but the two circuits were only out of parallel when changing from one section to the other.

*Mr. A. P. TROTTER wished to emphasise the remarks of Mr. Mordey by asking Mr. Sayers to incorporate in his reply, as printed, an estimate, or outline design, of a dynamo with his appliance, and of a dynamo as constructed according to the best theories.

*Mr. SAYERS, replying to the discussion, said he did not know in what terms to express his appreciation of the exceedingly kind way in which his Paper had been received. Dr. Thompson had very kindly suggested a diagram which was very highly appreciated. His (the speaker's) own diagrams did not seem to have been very easily understood. He thought he might say that, if those diagrams were difficult to understand, they represented everything that happened, and that was not true of any other diagrams that had been suggested. Another point of Dr. Thompson's was the use of a dummy section where driving pins were used. Mr. Swinburne also referred to the dummy section, and confirmed Dr. Thompson's view that it was useless. He (Mr. Sayers) had not tried it; he did not believe in armatures with irregularly spaced windings, but he had offered the idea to those who seemed still to find it necessary to adopt irregularly-spaced windings. Mr. Swinburne thought they might be troubled in future with his (Mr. Sayers's) arrangement, with hysteresis in the flux horn. He, however, had never found the slightest sign of heating, either in the flux horn or any other part of the field-magnet surface, provided the air space was not less than two-thirds of the width of the slot. He would qualify that by saying that it was also necessary that the area of the teeth should be sufficient to carry the induction. He thought that was a point which had been overlooked by some of those who had spoken, especially those who complained of the heating of the teeth. He had never found that the teeth in slotted armatures heated at all, and he thought the reason was that he had always observed the necessity for making the sum of the area of the teeth equal to the cross-area of the core. They had a certain amount of induction to pass through the armature, and, if they were going to pass it through the teeth, it was quite evident that they must be as careful in making the teeth large enough to carry the induction as they were in making the core large enough. He was very much obliged to Mr. Swinburne for pointing out that in a slotted armature there was no force exerted on the wire; that was a point which had not occurred to him, but it certainly seemed a very strong one in favour of a construction in which the wires were either wound through holes or in slots. Mr. Mordey suggested that it was of no practical use in putting the whole of the excitation on the armature. He (Mr. Sayers) quite agreed with him, more especially with regard to small machines. The reactions upon which he depended in his device would be greater in large armatures than in small ones. The large machines had behaved quite as well as, if not better than, the small ones. Mr. Mordey also thought there would be difficulty of insulation. He (Mr. Sayers) admitted at once that he had never made any very high-pressure machines with wires wound into slots, but he could not see any possible difficulty about getting good insulation. The insulation of the armature he had brought to the Institution was over 2½ megohms. He might say here that, although with machines as designed at present it was quite true that space was most valuable, it was nothing like so valuable when they adopted a hole-wound dynamo. With an armature with an ordinary air space, if they increased it, they must put more ampere-turns on the magnets. But if they were going to run with a smooth-cored armature, there was nothing to prevent them from increasing the diameter of the armature. They could make deep, narrow slots, and put almost as much copper in as they liked. If they put another half-inch on to the diameter of the discs it did not increase the cost of the machine to any appreciable extent. There were a few more pounds of charcoal iron discs, but there was no other expense in proportion. He had not thought Prof. Ayrton's proposal out properly, but he thought that arrangement of putting a cell in between two brushes could not work at all, and for this reason: they could not alter the current which was flowing in the coil; they could not perform the commutation without the identical current flowing through the circuit. He thought if they worked it out they would find that, and, consequently,

Digitized by Google

the resistance they were obliged to put in was absolutely fatal. Mr. Snell also thought he was wrong in going back to the toothed armatures; what he had said about the possibility of increasing the diameter of the armature without making a substantially bigger machine answered him to some extent. Prof. Forbes spoke of an alternating-current motor in which a somewhat similar device to his had been used. He might say he had also been on that track. Three years ago he designed a machine (which was never made) on those very lines. He feared he could not do justice to Mr. Housman's remarks, although there was a great deal that was very interesting in them. One point that Mr. Housman brought out was that that reversal of the current in the section that was being commutated was nothing like a straight line. He (Mr. Sayers) was quite aware that it was not a straight line, but he thought he would be complicating his Paper far more if he attempted to go into such details. Mr. Housman still adhered to the idea that a considerable current was generated in the short-circuited coil when passing the brush. He (the speaker) could not see how that was possible, because if the machine were running with the brushes in the proper position—he meant a sparkless position—when the coil became short-circuited there was an electromotive force being induced in it opposite in direction to the current which was flowing, consequently, instead of the current rising, as Mr. Housman represented in his diagram, it immediately began to fall. It might not fall in a straight line to the lower point, but it could not increase. It was carried through zero necessarily, and if the brush broke connection with it at the very instant when the current was at the right value in the opposite direction, there could not be any spark; the current was at zero, and the electromotive force of course was at zero as well. Mr. Housman cited as evidence the difference in speed between a generator and a motor. Now, there was a very simple explanation of this, which, so far as he knew, had not been published. If they had a shunt-wound generator to give 100 volts, then in the armature there would be $100 + C R_a$ = say 103 volts. Taking a motor with 100 volts, they had 100 volts on the shunt, exactly the same as with the generator; but they had 100 volts on the armature as well, consequently they had only got $100 - C R_a = 97$ volts. Consequently, they had there at once a difference of 6 per cent. in the speed, and when they considered that probably there was a loss of 3 per cent. in the armature, and probably another 1½ per cent. in the brush lead and surface resistance of the brush, they must see that they would probably get a difference of 10 per cent. in the speed between the generator and the motor with the same volts. With regard to reversing pole-pieces, he might remind them that Mr. Swinburne pointed out some time ago the difficulty, almost the impossibility, of designing them. With regard to Mr. Siemens's remarks, he had quite expected to hear that sort of thing said. He was not able to do what some gentlemen had asked him to do, to say distinctly what the saving would be. If they would take a license and experiment for themselves, that would be the simplest way to arrive at it. Mr. Mordey hit the nail on the head when he pointed out that what he (Mr. Sayers) had aimed at was reducing the air space.

The PRESIDENT (Mr. W. H. Preece) said it was quite refreshing to have heard in that room something novel about the dynamo. They had had Paper after Paper dealing with theory and the principles of the dynamo, but here they had something new, and which showed that, notwithstanding all the remarks that had been made, sometimes by himself, against the dynamo, the dynamo was not played out. What Mr. Sayers had shown them was that he was able to do something useful in another way, and he sincerely hoped Mr. Siemens would jump at Mr. Sayers's offer and let him have the skeleton of a dynamo in order that he might prove how the skeleton of a dynamo might be made more useful at a cheaper price, for, after all, it was a question of £. s. d. It was of no use bringing new facts before their meetings and discussing them unless they were going to be economical as well as useful. Let them hope that the offer would be the means of convincing the Institution that Mr. Sayers's method would be economical.

THE WEST COAST OF AFRICA CABLES.

On May 15th last a deputation waited upon the African Direct Telegraph Company with reference to the cost of cabling to the West Coast of Africa, and an extension of the Company's cables from Bonny to Old Calabar. The deputation consisted of Mr. W. F. Lawrence, M.P., and representatives from the Liverpool and Manchester Chambers of Commerce. The Directors present were Sir John Pender, G.C.M.G., M.P. (Chairman), the Marquis of Tweeddale, and the Hon. W. St. John Brodrick, M.P., Directors, and Mr. Thomas Fuller (the Managing Director).

Mr. W. F. LAWRENCE, M.P., introduced the deputation, who, in a printed statement, pointed out that the Company had four years ago been approached on the subject of reducing the rates for telegrams to the West Coast, and that they had then stated that the revenue from the West African traffic did not meet the working expenses, and without the subsidy of £19,000 per annum paid by Her Majesty's Government the Company could not exist; and the African Trade Section of the Liverpool Chamber of Commerce, which at that time approached the Company, forbore, under the circumstances, to press for the consideration of its views. Two years ago correspondence was re-opened with the Company, which was asked whether it was prepared to make a substantial reduction in the charges to British traders, provided Liverpool merchants and shipowners would undertake to pay in the year following such a reduction not less than the cost of their messages in the preceding year. This proposal, it was urged, had not been fairly considered by the Company. Before meeting the Company on the present occasion, a committee of the African Trade Section of the Liverpool Chamber had addressed a letter to all the members of the section (numbering 75 firms and individuals), and felt justified, from the nature of the replies received, in assuring the Company that all the principal users of the cable in Liverpool would consent to join in the guarantee referred to, in which the deputation felt assured of the support of Manchester, Glasgow, and London. In urging their views upon the Company, the deputation felt strongly that, in view of the growth of trade with West Africa, the large number of vessels employed on the coast, and the increased intercourse between the native populace with this country, any reductions granted by the Company under the guarantee proposed by the deputation would lead to an extended use of the cables, and thus result in an increased revenue. With regard to the suggested extension of either a landline or cable between Bonny and Old Calabar, Sir Claude Macdonald had furnished the Liverpool Chamber of Commerce with information as to certain details which enabled that body to recommend that a subsidy of £2,000 per annum should be paid by the Oil Rivers Protectorate to the Company in consideration of their agreeing to the extension. Old Calabar is the headquarters of the Oil Rivers Protectorate, and, in view of such an opening up as the extension of the telegraph would materially assist in bringing about, a considerable increase in trade would be reasonably anticipated.

These views were supported by, amongst others, Mr. FAIRLEY (of Manchester), who said that when the cable was established he was living as a resident in the Colony of Lagos, and could speak with knowledge of the appreciation there of the advantage of being in telegraphic communication with Great Britain. It was of immense service in many ways, and had increased commerce. But the expectation formed of increased opportunities of communicating with home firms had been much disappointed because of the high rates. They also felt sore that their French competitors were able to telegraph at much lower rates than they could. He hoped, therefore, in the interests of the Company itself, that serious consideration would be given to the grievances which the deputation had set out. It had been suggested in the statement read that a guarantee might be given with a view to protecting the Company from loss through reduction of the rates. He did not know how far that could be carried out, because all represented in the trade were not there, nor could they speak for all the interests involved, but he thought it was worth careful consideration whether such a system might not offer a solution of the whole matter. He would like to take this opportunity of saying that the native people were very fond of communicating with one another, and would do so if cheaper rates were granted. Members of the same family were distributed along the coast over a distance of perhaps 2,000 miles, and the Company would create a revenue not to be despised by cultivating traffic from this source. They did not expect the Company to work for nothing, but on the broad grounds of policy they urged a considerable reduction in the rate.

Sir JOHN PENDER, G.C.M.G., M.P. (Chairman of the Company), in reply, said: I can only assure you, gentlemen, that we are very glad to see you, and delighted to hear your views. The question that you have been broaching to-day is one that has been so often put before me that naturally I have got some little experience of what reductions in rates lead to. I may say at once that if you could persuade the Government to take a proper view of what they ought to do, I am quite prepared to deal with it. It is their duty to develop trade in every part of their Colonial possessions, and we have the same policy in regard to extensions of our system, and would be willing to make the connection you suggest if we saw that it would lead to the result you anticipate. It is the proprietors of this Company who have found the half-million of money necessary to establish this system, and unless we meet them with dividends, you may depend upon it, we do not get a cordial reception. I am quite sure, if you were standing in my place, you would not advocate any policy which you felt would not yield a moderate return upon the capital invested, and the Directors of companies, more particularly, have a double duty to be cautious because they are not dealing with their own money. Now the facts are very simple indeed. If you were to get the Government to guarantee the traffic something might be done, but when I tell you that for the first three years we paid no dividend, in 1889 2 per cent., in 1890 and 1891 4 per cent., you will see that we have no margin justifying us in incurring any risk of loss. Since we started, repairs have cost us £35,000, and another Company with which we work has spent since 1889 £25,000 in maintaining their system, so that the repairs of cable on that coast has involved the expenditure of the enormous sum of £60,000, and at the present time we have a ship making a repair just off the Congo. Now you say to me, "Reduce your rates to half and you will double your revenue." Well gentlemen, we have tried this with the Australian Colonies. We agreed if they would guarantee a certain revenue we would reduce our rates from 9s. 4d. to 4s., but after the low rate was in operation two years they came to us and begged us to somewhat increase our rate, because the loss was too heavy for them to bear. In the case of an enterprising people like the Australians, we have full confidence that the result will eventually justify the experiment, but I have never known the black races do much for submarine telegraphy. They have not done so either in the West Indies or anywhere else. The interests which you represent are, telegraphically, comparatively small. Liverpool only contributes about 15 per cent. of our income, small as it is, and Manchester figures for only a small proportion also. Let me tell you also, that but for two factors this Company would not have been able to exist. The first is the guarantee from the Government, and we accept all the responsibility which Mr. McArthur has alluded to, because if we saw any way in which we could develop traffic we should be the very first to encourage it. The guarantee proposal is not business because it would be an individual one, and would, therefore, not be a workable guarantee at all. I should require to ask who is to guarantee the guarantors. But if you will go to the Government and get such a guarantee as will enable us to earn a fair—not extravagant—dividend, we (the Company) will take some portion of the risk, believing that there is a development to work for. Germany came to us very much as you have done, but they gave us £6,700 per annum towards a cable. The reduction of rates to the Australian Colonies had resulted in a large increase, but not enough to recoup us for the loss made by the reduction

Digitized by Google

of the rate. You have made a strong point about the difference of rates as compared with the Portuguese and French colonies, but it is the Governments which are bearing the loss in connection with these low rates. I may explain to you that there are two *régimes* established by the International Telegraph Convention, namely, the European and the extra-European. The first applies primarily to the whole of Europe, and affects our system wherever we are in competition with European land systems. The African Direct Company works under the extra-European *régime*, but France and Portugal have chosen to regard their West African cables as forming part of the European *régime*, and consequently their rates are lower than ours; but Governments have got long purses, and can do what it is not in the power of a company to do. I do not say that Portugal has got a very long purse, but at any rate she does very bold things in telegraphy, and if a loss occurs it falls upon the Government, whereas in our case it would fall upon our shareholders. I therefore put it to you, gentlemen: How could we agree to a reduction when we pay our shareholders such an insignificant dividend? We are not in a position to lay by any reserve, and we find the waters in which our cables are laid are not by any means favourable for maintenance. I do not see myself that the position of the West African cables is at all encouraging, and I am sorry I cannot hold out any hope to you of the rates being reduced at present. I must again turn your attention to the Government, who have got power and can afford to do it. The subsidies from France and Portugal amount together to £39,208, whilst that from Great Britain is only £19,000. I should mention also, that by making our line part of an alternative route to the Cape we have secured an addition to our revenue, without which we should have been in a much worse position. I do not see the amount of telegraphy in your African trade which would warrant us in making the changes you suggest.

With regard to the extension of the cable from Bonny to Old Calabar, I think if you were to get the Government to give a subsidy of £2,000, in addition to what Sir Claud Macdonald offers, something might be done. Very often if the locality will do something towards such an object, the Government will do something too. If we were to make the reductions you suggest, it would affect the whole of our system. No merchant trading to India or China but would come to us and say: "You are taking such and such a rate to West African ports, and we do not see why you should not reduce the Indian and Chinese rates also." The merchants there are just as sharp as elsewhere, and we get letters frequently asking us to consider seriously whether we cannot meet their wishes, but we have to consider all these things as a whole. There is another very important point, and that is that if the messages were of the same average length as they were in the early days of submarine telegraphy we should be doing very well indeed, but there is not one of you gentlemen who has not adopted a code system, and you will admit that it does not in reality cost you anything like the charge per word we are making. With the elaborate codes you use, the charge per word is more like 9d. than 9s.

Mr. TUNNICLIFFE (of Liverpool) said his firm paid the Company £1,414 for telegrams during the year 1891-1892, and had paid since then for the half-year £687. Sir John had referred to the question of coding, but his Association found that frequently it would be a great deal better to send the whole of the message in clear language. Supposing the Company had a substantial guarantee in respect of a reduction to the Oil Rivers they would get more than they now received. In the event of an extension to Old Calabar he thought there would be a still greater increase. While the African Direct Company's rate to Lagos was 8s. 10d., the French Company's charge was only 6s. 3d. He would, therefore, ask if the Company could not put the Lagos merchants on the same terms as the French Company would do by transmission from Porto Novo, or otherwise, as a matter of economy, they would be compelled to resort to the latter route.

Sir JOHN PENDER: If you will get our Government to do for our trade what the French and Portuguese Governments do for theirs, and submit some scheme of guarantee of a practical nature which we can consider, we will do everything in our power to meet you.

Mr. LAWRENCE thanked the Chairman very cordially for the way in which he had received them. No doubt, some were disappointed that they had not received more encouragement, but they trusted time would show that they were right.

The deputation then withdrew.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *May* 19, 1893.

Electric Railway Building.—The building of electric railways has developed into a craze with us, and new projects are put on foot almost by scores daily. The prevalent topic nowadays is of "networks," and every ambitious town endeavours to become a radiating centre for roads leading into the rural districts, connecting the smaller towns with it. Many companies have also been formed for more ambitious undertakings, such as roads a hundred miles or more in length. As a consequence of this, the two great electric railway manufacturing companies are overloaded with orders; the General Electric Company reports unfilled orders for 2,500 railway motors and 127 railway generators, and the Westinghouse Company states that the orders it has on hand, with those received since April 1st, amount to $3,028,000, which is about double the figures for the same date last year.

The American Institute of Electrical Engineers.—This Institute held its annual meeting and election on May 16th and 17th, at which Prof. Edwin J. Houston was elected president for the ensuing year. Seven Papers were read, of which Prof. Carpenter's, "On the Variation in Economy of the Steam-Engine due to Variation in Load," and Prof. Pupin's, "On Practical Aspects of Electrical Resonance," were the most important. Prof. Carpenter developed formulæ, by means of which, if the usual data of a steam-engine at normal power is known, the water consumption, when run below the normal, may be determined. The Paper of Prof. Pupin was read in his laboratory at Columbia College, and was illustrated with many interesting experiments; among other things, the Professor illustrated the effect of capacity on alternating currents, increasing the electromotive force from 80 volts to above 1,000. The Professor also illustrated his method of harmonic selection; by means of a telephone and tuning-fork the adjustment of his apparatus could be so made that a wave of a definite periodicity could be easily selected.

The Westinghouse and General Electric Companies.—The sensational charges made against the General Electric Company by the Westinghouse Company have received no new developments. The General Electric Company was accused of having spies in the works of the Westinghouse Company for the purpose of stealing the plans, proposals, &c., of the latter, thus placing the latter Company at a great disadvantage in competition. A legal search of the premises of the General Electric Company was made, and a number of alleged stolen plans recovered, and the entire matter is now in the hands of the legal authorities.

The Electric Displays on the British Warships.—During their stay in New York the British warships greatly enhanced the prestige of the British Navy with the public by their brilliant electric-light displays. Although an attempt in this direction was made by all the vessels, including American, the British ships overshadowed all others to such an extent as to excite general comment.

CORRESPONDENCE.

COOKING AND HEATING BY ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The error in my letter published in *The Electrician* of May 19th, stating "one quart" instead of "one pint," is so palpable that every engineer must have known what was meant. The heat units generated by the current mentioned at 100 volts, would boil about 1 3lb. of water at 60°F. in ten minutes, but allowing for loss of heat, one pint could easily be boiled in this time. I do not, however, consider that the ordinary forms of kettles, saucepans, &c., are the most suitable for electrical heating; even the gas engineers have accustomed us to large flat-bottomed apparatus not previously employed. I am now making a new type of boiling arrangement specially suitable for use with electric heaters, which will, I believe, be a great advance on all others. It is interesting to hear from so eminent an authority as Mr. Thomas Fletcher that coal cannot be compared with electricity. This is exactly my opinion. Just as gas, when used for boiling purposes, affords many advantages over coal, so electricity will outstrip its rival for heating, as it is now doing for lighting.

It is not my intention to enter into a long controversy upon the merits of electricity in its latest phase, for this is unnecessary. The inquiries and orders we have in hand are sufficient proof of the public interest in this new departure. It is a mistake to consider that the expenditure of a few pence extra in cooking a dinner will deter those who have electricity available from using electrical cooking apparatus, particularly when it can be shown that the food is cooked in an absolutely pure atmosphere and in the most perfect manner. There is no

Digitized by Google

doubt that the old adage of "the proof of the pudding is in the eating" comes in with greater force in the present instance than is often the case.

Full particulars of trials will be published shortly, and I prefer to let these speak for themselves rather than discuss the theoretical possibilities of using electricity in this direction. The cost of using the apparatus is, of course, an important item; but I am satisfied that wherever the current is sold at a reduced price during the daytime, when most cooking operations are carried out, it can be used in competition with many other forms of apparatus now employed.

I remember, some ten or twelve years ago, that we were treated to long articles in journals interested in gas supply, *proving conclusively* (so they said) that electricity could never be supplied at a price that would be cheap enough to bring it into use for lighting purposes. The same thing is now happening with regard to the use of electricity for cooking and heating; but, as current is not only available, but in extensive use at the present time, I have no fear that as soon as the advantages of the electrical cooking and heating apparatus are known, electricity will be used for these purposes also.—Yours, &c.,

H. J. DOWSING.

London, E.C., May 31, 1893.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I certainly did not intend to use hard words about Mr. Dowsing's communication. I took his figures, and gave the comparative cost on his basis, which, it appears, is not correct. I do not profess to be an expert in electricity. It is not necessary to obtain the "specific heat of a mutton chop." This will be for practical purposes identical with that of water, of which it is largely composed. The actual heat used in cooking a mutton chop can be calculated with the greatest ease by weighing before and after cooking, and calculating the heat expended on evaporating the water, as almost all the work is expended on evaporating the necessary part of the water from the meat. Those who are attempting to make electrical cooking popular, must not forget that in this country, at least, stewing and cooking in close vessels, covered with non-conductors, is by no means popular, although useful to a limited extent for certain classes of work. Mr. Binswanger states that he is making an apparatus which will "cook" a small leg of mutton and about 5lb. of potatoes and cabbage with an expenditure of about two-thirds of a unit, say, 3d. In Dr. Kinnear Clark's report to the Committee of the Gas Institute (*see* Vol. I., p. 128) a test was made by roasting in an open chamber, by *radiant* heat, 7lb. 7½oz. of mutton, grilling two soles (1lb. 14oz.), roasting 5lb. of potatoes, and baking a rice pudding, a rhubarb tart, and some puff pastry, the gas consumed being 24·9 cubic feet, and the cost less than one penny. I should not have entered into the correspondence but for the fact that the duty of other fuels than electricity was being misrepresented, and I simply furnished the figures for calculation to prevent future errors. The quality of electrical cooking will no doubt be fairly judged on its own merits; the cost in many cases is not important, but if the question of cost is brought forward it should be done so fairly and from proper data which can be verified.—Yours, &c.,

Warrington. THOS. FLETCHER.

SUSPENSION WHEELS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your announcement of the death of Mr. E. A. Cowper, whose loss we all very much regret, you mention that the invention of tension wheels for bicycles in 1868 is attributed to him. Without detracting in the least from the importance and value of the late Mr. Cowper's numerous and useful inventions, I wish to mention that tension wheels were made between 1840 and 1850 by William Worby, at Ipswich, the inventor of numerous machines and implements of great practical success. In 1867 he gave me a pair of what he called his suspension wheels for a tricycle I was then about to make.—Yours, &c.,

W. WORBY BEAUMONT.

London, May 29, 1893.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

The 1893 Edition of "THE ELECTRICIAN" Electrical Trades Directory and Handbook is NOW READY. This useful book contains over 1,000 pages, and several new and handy features have been added. Price 7s. 6d., post free 8s. 3d.; abroad 8s. 10d. *Comparison with any similar electrical publication is specially invited.*

TENDERS INVITED.—The Urban Sanitary Authority of the Borough of Portsmouth invite tenders for the supply and erection of electric cables (both high and low tension), conduits, feeding boxes, &c. Copies of the specification, plan, &c., can be obtained of Mr. Alexander Hellard, Town Clerk, at the Town Hall, Portsmouth, on and after the 5th inst., and other information can be obtained of Messrs. Kincaid, Waller and Manville, 29, Great George-street, Westminster. Tenders must be in by 10 a.m. on Friday, the 23rd inst.

——— The Mayor, Aldermen, and Burgesses of the Borough of Harrogate invite proposals from persons or companies willing to undertake the duties and responsibilities of the Harrogate Electric Lighting Order, 1891. Further particulars are given in our advertising columns, and a schedule of terms and conditions can be obtained of the Borough Surveyor. Proposals must be sent in to the Chairman of the Electric Lighting Committee not later than noon on Thursday, 15th inst. Mr. George Wilkinson, M.I.E.E., is consulting electrical engineer.

——— The Electric Lighting Committee of the Halifax Corporation invite tenders for the supply and laying of a system of underground mains, pipes, manholes, &c. Some particulars are given in our advertisement columns, and forms of tender and all other information can be obtained of Mr. T. P. Wilmshurst, A.I.E.E., borough electrical engineer. Tenders must be sent in to Mr. Keighley Walton, Town Clerk, Town Hall, Halifax, not later than July 1st next.

——— The Caledonian Railway Company invite tenders for stores for twelve months from August 1st next, including telegraph and electric appliances, iron wire and strand, indiarubber, lamps, and lamp furnishings, tools, timepieces, gas and water fittings, bolts and nuts, rivets, &c., &c. The list is set out in our advertisement columns, and specifications and forms of tender and all further information may be obtained after the 5th inst. from Mr. J. Lorimer, superintendent of stores, Caledonian Railway, Charles-street, St. Rollox, Glasgow. Tenders must be sent in to Mr. J. Blackburn, secretary, 302, Buchanan-street, Glasgow, not later than Monday, the 19th inst.

——— The Corporation of Cardiff invite tenders for boilers, engines, machinery, and electrical apparatus. Tenders must be in by Monday, the 19th inst.

——— The Directors of the North-Eastern Railway require tenders for the supply of telegraph apparatus and telegraph wire and line stores during the six months July-December, which tenders must be in by the 6th inst.

——— *Public Lighting.*—The Corporations of Great Grimsby and Norwich and the Local Board of Bishop's Stortford invite tenders for the public lighting of their districts. No reference is made in advertisements as to whether electric light, gas, or oil will be adopted. Tenders must be sent in by June 9th, 10th, and 17th respectively.

TENDERS ACCEPTED.—The Building Committee of the Free Library and Museums Committee of the Carlisle Town Council have accepted the tender of Messrs. Latimer Clark, Muirhead, and Co. (Limited), London, for the work in connection with the installation of the electric light at Tullie House, for the sum of £1,450. This tender does not include the foundation, masonery and joinery work, but includes gas engines and the provision of duplicate plant. The accepted tender was the lowest of more than 20 sent in.

——— The Edinburgh Town Council have accepted the tender of Messrs. McCulloch, Sons, and Kennedy for the electric light installation at the Powderhall Refuse Disposal Works, for the sum of £354. 18s. 1d.

——— The tender of Callender's Bitumen, Telegraph, and Waterproof Company (Limited) has been accepted by the Hull Town Council for the necessary work in excavating for the extension of the electric light through various thoroughfares in the Council's district at £1. 19s. 6½d. per yard.

BANKRUPTCY.—The receiving order in the estate of Mr. C. J. Allport, electrical engineer, of 24, Woburn-place, Russell-square, has been discharged, the debtor having agreed to pay 20s. in the £ within a fortnight of approval by the Court.

Digitized by Google

APPOINTMENTS VACANT.—Particulars are given in our advertisement columns of several vacant appointments in the Indian Telegraph Service.

REMOVAL NOTICES.—The United Electric Light Company, agents for the Watt arc lamp, have removed their offices to 5, Featherstone-buildings, Holborn, W.C.——The Machinery Purchase Hire Company is removing from 147 to 46, Queen Victoria-street, London, E.C.

APPOINTMENT.—Mr. W. J. Corse, electrician, of Old Town-street, Plymouth, has been by Royal Warrant appointed Electrical Engineer to the Duke of Edinburgh.

PATENTS FOR SALE.—Messrs. Danger and Neville, of 41, North John-street, Liverpool, have for disposal the British Patent, No. 17,740, 1890, for rainbow letters and electrical advertising devices.

——— Messrs. James A. Brown and Co, of Chesterfield House, Great Tower-street, E.C., have for disposal patent rights in Great Britain, by which it is claimed that incandescent lamps can be repaired or supplied to consumers at 1s. each, net.

ELECTRICAL TRADES' UNION.—At the Conference of this body, held at Newcastle, a discussion took place on the subject of admitting electrical appliance makers to the Union, and it was decided to admit this branch. The Conference rejected the proposal for adopting the apprenticeship system for electric light wiremen. It was further agreed, on the question of the admission of females to membership, that they should be organised as electrical operators. Mr. A. J. Walker was re-elected as general secretary, and Mr. A. B. Johnson as organiser. Mr. W. T. Gooday was elected President, and Mr. A. Senior Vice-President, of the next Conference, which is to be held at Birmingham.

COLLIERY PLANT.—The Shillbottle Colliery Company have decided on putting down an electrical pumping plant for their colliery capable of delivering 200 gallons of water per minute against a head of 185ft. Messrs. Ernest Scott and Mountain (Limited) have secured the contract for this work, and also for a coal-cutting plant for a firm of coalmasters in Scotland.

EDISON AND SWAN COMPANY.—We have received a copy of the latest edition of the price-list issued by this Company. The new list is Section 5, and deals with brackets, standards, electroliers and fancy shades. The list is full of illustrations of a very large variety of fittings, many of which are of elegant design, a remark which particularly applies to the brackets illustrated on pages 10, 11 and 12, and to a number of the electroliers shown in the list.

MESSRS. JOHN H. HACKWORTH AND CO.—We are asked to state that this firm have acquired the business of the Machinery and Hardware Company (Limited), of Queen Victoria-street, and that they will in future carry on the business at 46, Queen Victoria-street, E.C.

THE GENERAL ELECTRIC COMPANY'S CATALOGUE.—This very elaborate catalogue consists of some 400 quarto pages, and we are informed that it contains over 10,000 illustrations and 50,000 prices. It consists of six divisions, which deal with (1) electrical supplies and wiremen's sundries, (2) electrical plant and machinery, (3) electrical fixtures and glassware, (4) electric bells and accessories, (5), telephones and accessories, and (6) electro-medical apparatus. One of the features of this catalogue is the great variety of the minor accessories which are fully illustrated. A large portion of the goods described are made by the General Electric Company, but, of course, there are many articles, such as engines, dynamos, glassware, &c., for which they act as merchants. Not only have the names of the makers and other designations been carefully omitted, the "Hedgehog" transformer, for example, appearing as an "open-circuit" transformer, and the Willans engine as "closed type engine," but the General Electric Company have suppressed their own name in the body of the catalogue, enabling the trade to use it as a book of reference for their customers. To many of the well-known specialities of this Company it is unnecessary to allude. A large variety of switches are described, and the excellent H. I. cut-outs and ceiling roses, with a porcelain partition between the wires. The General Electric Company are erecting a large factory for the production of glow lamps as soon as the patent expires, and promise "Stella" lamps of 3 watts per candle, or even 2½ watts per candle with a somewhat shortened life. Among the testing instruments we notice that a few Evershed ohmmeters are kept in stock in London for letting out on hire, a great convenience to those who do not often require these instruments. A page of sample wiring estimates is given, but it is a pity that such low figures should have been quoted. They may be based on good work, but in the large majority of cases they would only tempt contractors to make a profit out of extras, for the estimates for labour seem quite inadequate. A very large variety of stoneware insulators are given, and a good selection of insulator fittings. Among other novelties we notice that a "tubular system of wiring," recently described in our columns, is offered; this consists of *papier maché* tubes impregnated with bitumen. These may be let into plaster, but leave the wires accessible, the bends and elbows being well rounded. Among the accessory fittings for electric light we notice some neat cord-shorteners and insulating flanges for insulating gas fittings. The fittings of the General Electric Company are all provided, unless specially ordered, with ½in. tubes, allowing room for good insulation, and 26 threads to the inch are always used. In this and other matters great care has been taken to standardise appliances so that interchangeability is secured. This catalogue should form a useful price-book for electrical engineers, contractors, and exporters.

ABERDEEN.—The Town Council, at their last meeting, discussed the question of the electric light, and, amongst other matters, decided to appoint an electrical engineer to take charge of the electric lighting department, at a salary of £200 per annum. Further particulars will, we understand, be shortly announced.——The Northern Co-operative Company have received Porf. Kennedy's report on the proposed electric lighting of their extensive premises in Loch-street and Gallowgate. The initial outlay is estimated at about £1,400, and the annual cost at £270—a saving of £50 annually on the cost of gas. After discussing the report for some time, the Directors adjourned its consideration to a future meeting.

BOLTON.—The Corporation have, we understand, selected a site in the vicinity of Spa-road for the electric-lighting station, and progress is to be immediately made with the erection of the works, for which elaborate plans and particulars have been prepared by the borough electrical engineer, and are under the consideration of the Electric Lighting Sub-Committee. The system to be adopted has not yet been finally settled.

EXETER.—The Devon Standing Joint Committee have decided to light Exeter Castle by electricity, the installation to include the new offices, at a cost not exceeding £135. 11s.

GLASGOW.—The District Lunacy Board have further discussed the subject of introducing the electric light into the various buildings connected with the Gartlock Asylum, and have deferred their decision until certain matters in connection with the site for some buildings has been agreed upon.

HULL.—The success of the electric light in Hull is fully assured, and a considerable extension of the original area is now being proceeded with. The Town Council, at its last meeting, received an order from the Hull branch of the Bank of England for a large installation at the bank's premises.

LEEDS.—The new building in course of erection for the Medical Department of the Yorkshire College, at Leeds, is to be lighted entirely by electricity. The installation is to consist of about 750 lamps, the contract for which has been secured by Mr. T. Harding Churton.

LIVERPOOL.—The annual meeting of the proprietors of the Liverpool Library in Bold-street has been held, and the Directors stated that the electric light has been introduced at a cost of between £80 and £90, and that the Committee of the Library believe that this expense will be more than recouped in a very brief period by the saving in book-binding alone, which for the past year amounts to about £120. The report continues "it has been a source of regret to successive Committees to find that bindings of a large number of books have become seriously injured by the gas. The change to electric lighting has induced the Committee to have a number of the most important books rebound in a superior style." Other Library Committees please copy.

LLANGOLLEN.—At the last meeting of the Local Board a Committee was appointed to consider the question of supplying electric light to the town. It is proposed to use water-power, and if the scheme proposed by Mr. Brayne, of Liverpool, is adopted, the water-power plant will be erected on the River Dee, immediately above the Llangollen Flour Mill. The water-power plant is estimated to cost about £800, and the complete scheme about a further £1,600.

PENYMYNYDD.—A new electric organ has been erected in the church of St. John, and at a recent trial of the instrument, at which Mr. Gladstone assisted, great satisfaction was expressed.

NEWARK.—An application has been made by the promoters of a scheme for the electric lighting of this borough to the Urban Sanitary Authority asking their consent to the promoters obtaining a Provisional Order to enable them to carry out the scheme. The matter was referred to the Lighting Committee.

NORWICH.—At the last Town Council meeting a discussion arose as to the renewal of the Gas Company's tender for lighting the public lamps, and a member of the Council hoped that before next year some arrangement would be entered into with the Local

Digitized by Google

Electric Lighting Company for the lighting of the principal streets by electricity. On behalf of the Gas Committee, Mr. White stated that before the new contract with the Gas Company expires efforts would be made to complete arrangements with the Electric Lighting Company in the direction referred to.

OSTEND.—It is stated that the municipal authorities contemplate inviting tenders for the electric lighting of the city.

RUGBY.—A proposal to light Rugby School by electricity has been before the governors for some time past, but has not, we understand, met with complete approval. It is now being energetically promoted, and the question will be definitely settled shortly.

SOUTHPORT.—A special meeting of the Town Council was held on Tuesday last to consider the question of adopting an electric lighting scheme for the town.

TIVERTON.—The Town Council had under discussion on Wednesday a report of the Electric Lighting Committee, who recommended the adoption of a scheme which, while costing £13,700, would not, in the Committee's opinion, be any additional burden on the rates. It was ultimately decided, however, that the scheme be postponed for a twelve-month.

WORCESTER.—The Guardians having negatived the proposal to instal the electric light in the workhouse building, a deputation from the Town Council has been appointed to wait on that body to prevail upon them to adopt the electric light, and the Guardians propose to find accommodation for an engine and dynamo capable of supplying the necessary number of lights, pending the completion of the Council's suggested electric lighting scheme. The Council propose to arrange with the Brush Company to supply the plant at an estimated cost of £200. At the last meeting of the Board of Guardians the matter was not finally decided, and the deputation appointed by the Council will probably succeed in their mission.

PATENT RECORD

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

May 13, 1893.

9,638. E. J. HALL. London. Central office apparatus and circuits for telephone changes. [Date applied for under Patents Act, 1883, Sec. 103, October 13, 1892, being date of application in United States.]

9,639. E. J. HALL. London. Trunk-line signalling apparatus and circuit for telephone exchanges. [Date applied for under Patents Act, 1883, sec. 103, October 13, 1892, being date of application in United States.]

9,640. E. J. HALL and F. A. PICKERNELL. London. Electrical signalling apparatus and circuits. [Date applied for under Patents Act, 1883, Sec. 103, October 13, 1892, being date of application in United States].

9,641. E. J. HALL and F. A. PICKERNELL. London. Busy signals for telephone circuits. [Date applied for under Patents Act, 1883, Sec. 103, October 13, 1892, being date of application in United States.]

May 15, 1893.

9,662. J. E. B. WALKER. Birmingham. An electric lamp for bicycles, tricycles, and all kinds of rolling stock.

9,664. CH. MELLIER and Co. (Godfrey, Dinlacher, and B. A. Lacoste.) London. Improved plug for combination electric candle fitting.

9,670. S. D. WILLIAMS, W. J. CLAPP, and G. H. LLEWELLYN. Newport, Mon. An electro-chemical purifying process in iron making and for other purposes.

9,699. W. GORDON. London. Improvements in connection with connecting joints for electric mains, telegraph wires, and telephones.

9,716. W. DEFRIES and V. J. FEENY. London. An improved method and apparatus for the production of electrical effects in ballets and other theatrical representations.

May 16, 1893.

9,753. W. E. AYRTON and T. MATHER. London. Improvements in electrical and other measuring instruments and apparatus.

9,779. C. A. ALLISON. London. Circuit switch. (The Electrical Speciality Company, United States.)*

9,780. F. V. WOOD. London. Improved electrical apparatus for obtaining light.

9,805. SIEMENS BROS. and Co. (LIMITED) and F. JACOB. London. Improvements in contacts for making and breaking electrical circuits.

9,810. H. C. BULL. London. Improvements in, or connected with, incandescent electric lamps.

9,818. J. F. CUMMINGS. London. Improvements in underground conduits for electrical conductors.*

9,819. W. P. HALL. London. Improvements in electric circuit controlling devices.*

9,821. H. H. LAKE. London. Improvements in galvanometers (Whitney Electrical Instrument Company, United States.)*

May 17, 1893.

9,864. R. G. EVERED and A. WATSON. London. Improvements in electrical switches.

9,906. D. G. FITZGERALD. London. Improvements in the manufacture of elements or electrodes for voltaic batteries and electrolytic decomposition cells.

May 18, 1893.

9,965. A. LONGSDON. London. Improvements in or connected with the working and welding of metals by electricity. (The firm of Fried Krupp, Germany.)*

9,997. S. COPETER and H. NEHMER. London. Improved method of generating electricity direct from heat.

May 19, 1893.

10,006. H. W. SWAIN. Runcorn. Fine art electro-plate.

10,015. R. E. B. CROMPTON and H. J. DOWSING. London. Improvements in apparatus for use in the utilisation of electrical energy for culinary purposes.

10,042. F. KING. London. Improvements in and apparatus for the manufacture of plates, grids or supports for secondary batteries.

10,043. H. W. BUDDICOM. London. A current governor for electromotors.

10,056. C. OLIVETTI. London. An improvement in commutators for electric machines.

May 20, 1893.

10,091. W. GREENHALGH. Leeds. Improvements in and relating to electromotors.

10,095. E. DE PASS. London. Improvements in electro-plating. (Hermann Thofehrn, France.)

10,107. J. H. KINSMAN. London. An improved telephone call.

10,129. H. EDMUNDS. London. Improved electrical conductor.

10,130. H. PIEPER. London. Improvements in means for supplying current for driving vehicles on electric railways or tramways.

10,131. W. B. SAYERS, H. A. MAYOR, W. A. COULSON and S. MAYOR. London. Improvements in the construction of armatures for dynamo electric machines.

10,142. W. FRITSCHE. London. Improvements in and relating to electric machines.

May 23, 1893.

10,147. F. DOWLING. London. Electric belts, corsets, and appliances.

10,205. F. L. and L. H. DYER. Electric steering gear.

10,207. A. C. SEIBOLD. London. Improvements in electrodes for arc lamps.

10,218. R. WOOD. London. Improvements in methods of regulating the distribution of electricity, and in converting its energy into that of light.

May 24, 1893.

10,242. C. ADAMS RANDALL. London. Improvements in telephonic apparatus.

10,283. J. E. HOFMAN. Liverpool. Improvements in and connected with the manufacture of electrode plates for secondary batteries.*

10,293. W. B. SAYERS. London. Improvements in dynamo electric machines.

10,304. J. LOBLEY. London. Improvements in lighting and extinguishing electric lamps for street lighting.

May 25, 1893.

10,336. C. L. ANDERS and W. KOTTGEN. London. Improvements in microphonic contacts.

10,347. H. K. SPANGENBERG. London. Improvements in or connected with battery switches.*

May 26, 1893.

10,363. F. T. SCHMIDT. Bradford. Improvements in electrically controlled arc lamps.

10,382. T. E. CARMICHAEL. An improved switch for electric appliances.

10,396. W. L. DUDGEON. London. Improvements relating to electric conductors. (La Société Anonyme: Cockerill, Belgium.)

9,569. SHREWSBURY and DOBELL. Electric batteries.

9,799. FITZGERALD. Electrolysis of alkaline chlorides.

10,022. GRIST. Electro-telephonic apparatus.

10,059. PAYNE. Electric conductors.

10,265. AYRTON and MATHER. Electrical measuring instruments.

10,738. EDISON and SWAN UNITED ELECTRIC LIGHT COMPANY (LIMITED) and GIMINGHAM. Electric safety lamps and batteries.

10,161. EVERSHED. Telegraphic communication with lightships.

10,472. EWING. Apparatus for electrical, &c., measurements.

11,085. WOODHOUSE and RAWSON UNITED (LIMITED). (Varley.) Electrical indicators.

11,382. NIEWERTH. Making chemical products by electricity.

11,487. JEFFRIES. Telephone, &c., poles.

11,532. BORSE. Storage batteries.

12,731. SIEMENS BROS. and Co. (LIMITED) (Siemens and Halske). Electrolytic extraction of zinc.

13,090. HEDGES. Incandescent electric lamp fittings.

22,838. DAY (Haynes). Telephonic apparatus.

1893.

449. STOREY. Electric motors.

1,229. LLOYD. Secondary batteries.

1,449. FOWLER. Electrical hose signalling apparatus.

2,672. BRADLEY and Others. Electric transmission of power.

4,818. DORMAN and SMITH. Electric switches, &c.

6,073. GWYNNE and KENNEDY. Arc electric lamps.

6,295. STOBER. Electric incandescent lamps.

6,031. MILLS (Courtenay). Transmitting electric currents.

6,478. THOMSON. Dynamo-electric machines, &c.

6,565. SIEMENS BROTHERS and Co. (LIMITED) and OBACH. Dry voltaic cells.

6,579. MITCHELL. Electrically heated radiator.

COMPANIES' MEETINGS AND REPORTS.

Reuter's Telegram Company (Limited).

The twenty-ninth ordinary general meeting of the shareholders in this Company took place on Wednesday at the offices, Old Jewry, under the presidency of the Hon. Mark F. Napier, M.P., in the absence, through indisposition, of the Chairman of the Company, Admiral the Right Hon. Sir J. C. D. Hay, Bart., K.C.B.

The SECRETARY (Mr. W. F. Bradshaw) read the notice calling the meeting, and the report of the Directors was taken as read.

The CHAIRMAN said: I have now to move the adoption of the report. I am sure you will all agree with me that it is a source of considerable satisfaction that the result of the Company's operations last year is so much more favourable than in 1891. The increase shown under the head of subscriptions, commissions, &c., affords, we think, the best proof of the sound state of the Company's business. On the other hand, the expenditure for telegrams and agencies shows an increase which it has not been possible to avoid, as, although peace was preserved, last year was throughout a period of anxiety and public excitement. We have little to report on this occasion in regard to the advertisement branch beyond saying that in the financial depression which prevailed last year it was impossible to make very great headway. Everything is, however, in readiness for an improved state of business, and agencies have been established, which will, we are confident, yield a good return in the future. Before concluding, I should like to say a few words in support of the resolution which will be moved in regard to the question of superannuation for the staff. Although an officers' life insurance and superannuation fund has been established since 1881, no measures have yet been taken to provide superannuation allowances to the staff. The scheme which has been drawn up provides that the staff shall contribute 2½ per cent. of their salaries to a fund to which the Company will contribute a like amount. As, however, the scheme, which is open for the shareholders' inspection, explains the matter in detail, I would only say that the proposal commands our hearty support, as we can conceive of no more efficacious method of attracting to, and retaining in, the service of the Company the class of men we want in our business than by assisting them to make provision for old age.

Mr. FREDERICK J. GRIFFITHS seconded the motion, which was at once unanimously adopted.

The CHAIRMAN then proposed a resolution authorising the Directors to affix the seal of the Company to an indenture, a draft of which had been already prepared, for adopting and giving effect to the superannuation scheme referred to. He stated that the Directors had no pecuniary interest in the proposal, and they had worked out the scheme solely with the view of making the provision in question for their officers.

Mr. GRIFFITHS seconded the motion.

In answer to Mr. LIDDON,

The CHAIRMAN stated that the Managing Director had just informed him that the amount paid by the Company under the scheme would be about £400 a year. A company of their standing was often called upon to make some allowance to old members of the staff, but the scheme now proposed would put an end to this.

The resolution was unanimously agreed to.

On the motion of Baron DE REUTER, seconded by Baron GEORGE DE REUTER, Mr. Griffiths was re-elected to his seat at the Board, and the auditors, Messrs. Welton, Jones and Co., were afterwards re-appointed.

Mr. LOVEDAY then proposed, and Mr. LIDDON seconded, a vote of thanks to the Chairman and Directors, and the motion was unanimously adopted.

The CHAIRMAN, in acknowledging the compliment, said that the Directors were doing all in their power, not only to maintain the Company on its present solid footing, but, if possible, to improve and strengthen it.

The meeting then separated.

Telephone Company of Ireland (Limited).

The fourteenth ordinary general meeting of this Company was held in Dublin on Saturday, Alderman V. B. Dillon (Chairman) presiding.

The CHAIRMAN said the meeting had been called to transact the ordinary business of the Company, and also to consider a special resolution agreeing to transfer their undertaking to the National Telephone Company. Before they proceeded to dispose of the ordinary business of the meeting he would say a few words in explanation of their position. It might seem strange that while the Company was in a prosperous condition, their earnings last year being £6,000 of net revenue—a sum sufficient to pay a substantial dividend on the capital—that the Directors should recommend the sale of the property. He trusted he would be able to show to the shareholders that they would be acting wisely in adopting the special resolution. They would remember that the ordinary capital was £200,000, divided into £25,000 preference and £175,000 ordinary shares. No money had been paid in respect of the ordinary shares, the preference shareholders receiving one ordinary share for each preference share, and one-half of the ordinary shares was allotted to the National Telephone Company. In 1883 this Company required further capital, and they issued more preference shares, making the 6 per cent. preference into 5 per cent., the preference capital being thus increased to £44,749. In 1889, when all the capital was exhausted, the Directors sought to obtain further capital, and decided to issue further preference shares, but only £14,000 was taken up. Debentures were also offered to the shareholders, but only £2,900 was taken up. He thought this justified the Directors in coming to the conclusion that the shareholders were not prepared to find any further capital. The Company had opened up business in Cork, Limerick, Dundalk, and Drogheda, and had laid part of the trunk line between Dublin and Belfast; and they had also entered into negotiations for an extension to Waterford, but capital was wanted for that. In the meantime they also required to make a considerable outlay in the switch room and to provide plant, and this meant additional capital outlay. For their day-to-day extension they had been obliged to appropriate the dividend which would ordinarily have been paid to the shareholders. That had enabled them to continue their operations without extending them for two or three years. But it was manifest to the Directors that they could not go on to properly develop the system without a large outlay, and that outlay, it was plain, could not be provided by the shareholders. They had been, therefore, driven to consider some course for raising further capital. They considered whether it would be more advantageous to purchase the property of the National Company in Ulster. He should say that their Company controlled the whole of Ireland except Ulster, and if they purchased the Ulster property they would have had to form a larger company, and raise further capital. The alternative was their selling their property to the National Telephone Company, who had acquired all the telephone property in Great Britain and Ireland, with the exception of that owned by the Telephone Company of Ireland. They had, therefore, entered into negotiations with the Directors of the National Company, and they had now concluded with them an arrangement which they considered fair and reasonable, having regard to the fact that the shareholders were not willing to provide further capital. It was rather fortunate when they were discussing matters with the National Company that they had in hand a substantial cash balance which they had retained, because it had enabled them to say "If you don't give us our price we will endeavour to go on for some time longer." The agreement provided that the management would still be left under the control of a local board, which for a period of five years would consist of the present Directors of the Company. He mentioned that because it was important that local control should should be preserved over the Company. He concluded by moving the adoption of the report (which appeared in the last issue of *The Electrician*) and accounts, which, after some discussion, was carried.

Digitized by Google

In reply to a shareholder, the CHAIRMAN said there was 2s. a share dividend due on each preference share, and they would get the ordinary dividend payable from January last.

Alderman V. B. Dillon and Mr. J. N. Keane having been re-elected Director and auditor respectively,

The CHAIRMAN proposed the resolution ratifying the provisional agreement for the transfer of the undertaking of the Company to the National Telephone Company (Limited), which was seconded and carried, and the proceedings terminated with a vote of thanks to the Chairman.

Elmore's American and Canadian Patent Copper Depositing Company (Limited).

The first annual ordinary general meeting of this Company was held on Tuesday at the Cannon-street Hotel, E.C., Mr. J. J. Atkinson presiding.

In moving the adoption of the Directors' report and accounts, the Chairman said he thought the shareholders would approve of the policy of the Board in deferring the erection of plant in America until the European companies had demonstrated the commercial value of the process. Otherwise they might have spent their money in putting up plant which would not have finally satisfied anybody, and in that way they also might have had to ask for more money, whereas they had spent very little of their working capital, and there was a strong probability that they would not need to spend anything at all on plant in America in order to sell their rights. Their American agents informed them that the quality and excellence of Elmore copper was undisputed; but before the parties desiring to acquire their rights would close as to terms, they must first see that the process could be utilised successfully on a large scale, such as could be shown in France or at Leeds. He was pleased to say that recently progress had been made. The English Company had had the whole of its preference shares subscribed, and they looked to see the business fully successful before the end of the year. As regarded the French Company, it was being taken over entirely by a new company formed in Paris, whose cash capital of £80,000 was over subscribed, and they were hopeful that that Company would soon be a success. Turning to the accounts, the Company had received £85,295 in share capital in cash, which was accounted for by £74,576 for their patents, £1,155 for plant, £7,000 lent to the French Company, £2,004 first establishment charges, and the cash in hand.

The report was adopted, after some discussion.

NEW COMPANIES, STATUTORY RETURNS, &c.

AFRICAN TRANSCONTINENTAL TELEGRAPH COMPANY (LIMITED).—The statutory return of this Company, made up to May 11th, and recently filed, shows that 34,816, out of a total of 140,000 shares of £1 each, were taken up. Upon 1,281 of these shares the full amount has been called, and upon the remaining 33,535 shares 5s. per share has been called, resulting in the payment of £7,664. 15s., and leaving £2,000 in arrears.

ALBERT ELECTRIC LIGHTING COMPANY (LIMITED).—The statutory and first annual returns of this Company, which have recently been filed, show that out of a nominal capital of £10,000, in £5 shares, 407 have been taken up. Upon 400 of these the full amounts have been called and paid, while no calls have as yet been made on the seven signatories' shares.

ASKWITH AND CO. (LIMITED).—The statutory return of this Company, made up to April 7, 1893, has just been filed. The nominal capital is £20,000, in £1 shares, of which 10,005 shares have been taken up, 5,005 shares have had the full amount called upon them, while a call of 12s. per share has been made on 5,000 shares, resulting in the payment of £8,005.

AUTOMATIC ELECTRIC RAILWAY SIGNAL COMPANY (LIMITED).—The statutory return of this Company, made up to February 22, 1893, has recently been filed. 4,905 £1 shares, out of a total of 10,000, have been taken up, of which 3,300 have been issued as fully paid. Upon the remaining 1,605 shares, a call of 10s. per share has been made, resulting in the payment of £787. 10s., and leaving £15 in arrears.

R. C. CUTTING, DOUGLASS, AND CO. (LIMITED).—The statutory return of this Company, made up to April 4, 1893, was filed recently, when 49 shares, out of a total nominal capital of £12,000 in £5 shares, were taken up. Upon 47 of these shares the full amounts have been called, and upon the remaining two shares a call of £2. 10s. per share has been made, resulting in a total payment of £240.

ELECTRICAL WONDER COMPANY (LIMITED).—The statutory return of this Company, made up to March 25th, has been filed. The nominal capital is £10,000, divided into 9,900 ordinary and 100 founders' shares, of £1 each. 5,000 ordinary and 100 founders' shares have been taken up, and the full amounts called, resulting in the payment of £3,736. 10s., and leaving £1,363. 10s. as yet unpaid.

GULCHER ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—A meeting of this (the old) Company is to be held at Messrs. Trinder and Capron's, 47, Cornhill, on the 30th inst., at 2:30, for the purpose of receiving an account of the winding-up and of the transfer of the business and assets to the Gulcher (New) Electric Light and Power Company (Limited).

INDO-EUROPEAN TELEGRAPH COMPANY (LIMITED).—The annual return of this Company, made up to May 12th, has been filed, and shows that, out of a nominal capital of £450,000, divided into 18,000 shares of £25 each, 17,000 of such shares have been taken up, the full amount called, and all calls (£425,000) paid. The return further states that share warrants, comprising 3,187 shares of £25 each are still outstanding, that share warrants to the total value of £200 have been issued since the making-up of the last return, and that share warrants, comprising 139 shares, have been surrendered to the Company since the last summary.

LANCASHIRE AND CHESHIRE HOUSE-TO-HOUSE ELECTRICITY COMPANY (LIMITED).—The annual return of this Company, made up to January 13, 1893, and recently filed, shows that the 100 founders' shares (which were issued as fully paid to the House-to-House Company), and the shares taken by the seven signatories, are the only ones taken up.

LONDON METALLURGICAL COMPANY (LIMITED).—This Company is to be compulsorily wound up.

MANLOVE, ALLIOTT, AND CO. (LIMITED).—The annual return of this Company, made up to May 6th, has been filed. The nominal capital is £100,000, in £10 shares, of which 4,599 have been taken up, 4,546 have been issued as fully paid, and £530 has been called and paid on the remaining shares.

PHONOPORE COMPANY (LIMITED).—The annual return of this Company, made up to December 31, 1892, was recently filed, the delay being due to the fact of the non-holding of the annual meeting. The nominal capital is £150,000, divided into 100,000 ordinary and 50,000 preference shares of £1 each, of which 90,000 ordinary and 28,063 preference shares have been taken up. 69,025 ordinary and 10,380 preference shares have been issued as fully paid. The full amount has been called on the remaining 20,975 ordinary shares, while a call of 10s. per share has been made on 17,683 preference shares, resulting in the payment of £30,218, and leaving £8,440 in arrears.

A. RANSOME AND CO. (LIMITED).—The statutory return of this Company, made up to May 10th, and recently filed, shows that 5,900 shares, of £10 each (the whole nominal capital), have been taken up, of which 5,593 shares have been issued as fully paid. The full amounts have been called, and all calls have been paid on the 307 remaining shares.

ROGER DAWSON (LIMITED).—The Statutory return of this Company, made up to May 15th, has been filed. Of the nominal capital of £15.000, in £1 shares, 14,993 shares were issued as fully paid, while £1 per share has been called and paid on the remainder.

ST. PAUL'S PRINTING AND PUBLISHING COMPANY (LIMITED).—The first annual return of this Company, made up to and filed on March 28, shows that 1,704 shares of £1 each, out of a capital of £10,000 in £1 shares, have been taken up, and the full amount called. The calls paid amount to £1,325, leaving £379 in arrear.

SPANISH NATIONAL SUBMARINE TELEGRAPH COMPANY (LIMITED).—The annual return of this Company, made up to April 13th, recently filed, shows that 23,719 shares of £10 each have been taken up out of a nominal capital of £500,000, divided into 49,900 ordinary shares of £10 each and 1,000 founders' shares of £1 each. 23,715 of these shares were issued as fully paid, while the full amount has been called and all calls paid on the remaining four shares. Share warrants to the total value of £22,990 are still outstanding, while share warrants comprising 55 shares have been surrendered to the Company since the making up of the last return.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).—The Directors of this Company have declared an interim dividend of 3s. per share, or at the rate of 6 per cent. per annum, free of income-tax, for the quarter ended March 31st last, and payable on the 24th inst. The transfer books will be closed from the 17th to the 23rd inst., inclusive.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended May 28th were £844, as against £713 for the corresponding period of last year, being an increase of £131. The total receipts for the half-year amount to £18,579, against £17,087 in the corresponding period of 1892, being an increase of £1,492.

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company invite subscriptions for £200,000 of the Four per Cent. Registered Mortgage Debentures (Mauritius subsidy) of £25 each of the Eastern and South African Telegraph Company (Limited) at par, payable 10 per cent. on application, 20 per cent. on allotment, 20 per cent. on the 27th inst., and the balance of 50 per cent. on July 25th. This issue forms part of a total of £300,000, to be secured by a first charge upon the subsidies amounting to £28,000 per annum granted by Her Majesty's Government for a period of 20 years in respect of the Zanzibar-Seychelles-Mauritius cables, and upon the net receipts from such cables. The interest is payable half-yearly on May 1st and November 1st in each year, and the principal is to be repaid on November 1, 1913. The proceeds of the issue are to be applied in part payment for the manufacture of laying of about 2,310 miles of cable to connect the existing lines from Europe along the East and West Coasts of Africa at Zanzibar with the island of Seychelles, and thence to Mauritius. A sinking-fund will be created to provide for the repayment of this issue. Prospectuses may be had of the bankers, Messrs. Barclay, Bevan and Co., 54, Lombard-street, E.C., or at the offices of the Company, Winchester House, Old Broad-street, E.C. The list of applications closes on or before four o'clock on Wednesday, the 7th inst.

Digitized by Google

STOCK EXCHANGE NOTICES.—Application has been made to the Stock Exchange Committee to allow the ordinary shares Nos. 1 to 15,000 of the Monte Video Telephone Company (Limited) to be quoted in the Official List.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—Th traffic receipts for the week ended May 26, 1893, after deducting 17 p cent. of the gross receipts, payable to the London Platino-Brazili Telegraph Company (Limited), were £2,422.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 786.—Vol. XXXI. FRIDAY, JUNE 9, 1893. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

The net outcome of the last meeting of the Electrical Trades Section has been the conversion of the Electric Traction Association into a special Sub-Committee of the Electrical Trades Section of the London Chamber of Commerce; a proceeding against which the General Manager of the National Telephone Company entered a vigorous protest, under the erroneous impression that the whole weight of the Chamber itself was to be thrown into the scale on behalf of a single trade. Enlightened self-interest and the support of the Municipal Corporations Association will, it is to be hoped, enable the tractionists to score a victory at the forthcoming Parliamentary inquiry; for it is tolerably plain that no one not immediately concerned cares much whether the telephone or the traction circuits are doubled. In either case "it will be good for trade," as some genial gentleman no doubt remarked when Nero fiddled whilst Rome burned. However, we have a shrewd suspicion that in the long run trade will benefit more by a healthy development of electric traction than by a Parliamentary benediction being given to single-wire telephony.

At the Royal Society's *conversazione*, on Wednesday last, the most interesting exhibit, from an electrical point of view, was a new instrument called the hydrophone, of which we gave a brief account in our issue of November 18, 1892. The purpose of this apparatus, which is the invention of Captain McEvoy, is chiefly to give warning of the movements of distant vessels, and to prevent surprise attacks. In principle it is very little more than a microphone connected up in series with a battery and telephone. All the contacts in the microphone are, however, metallic, and the apparatus is enclosed within a bell-shaped iron vessel, which is sunk to a suitable depth at the place at which the vibrations of the water are to be observed. Water does not enter the vessel, owing to its containing compressed air like a diving bell. The movements caused by the screw of a passing steamer agitate the loose metallic contacts in the microphone, altering their resistance, and consequently changing the current strength in the circuit connecting the apparatus with the shore. This change in current produces sound in a telephone placed in circuit in the usual way, or may be made to work a relay so as to ring a bell or flash a light, &c. The apparatus is simple and compact, and seems unlikely to get out of order. It is stated that a torpedo boat cannot approach within a range of half a mile of the submerged vessel, or a man-of-war within a distance of a mile, without the pulsations of the propellers being detected. The apparatus has been tried by military experts at Stokes Bay, and the sounds caused by various kinds of propellers have been distinguished at a distance of more than seven miles.

A new Harmonic Analyser, constructed at Zürich to designs by Prof. Henrici and Mr. Sharp, was also exhibited. By making the tracing point of this instrument travel once over a curve, the first *five* terms of the Fourier's series, which represents this curve, can be at once read off. On going twice more round the curve, the next five terms can be obtained. Naturally the instrument is most complicated. It, however, appears to work admirably, and will be very useful in many departments of scientific work. In electricity an important adaptation will be to analyse the shape of the curves representing alternating currents.

Mr. Nikola Tesla's lecture, delivered in February last before the Franklin Institute at Philadelphia, and before the National Electric Light Association in March, has now been published in the American papers, and the first part of an abstract of it will be found in another column. On the whole, it is a disappointment, but Mr. Tesla's work is difficult to appreciate. The lecture begins with a long introduction on the value of vision as a connecting link between our consciousness and the world we live in. This leads to the consideration of light, and our abstract begins with the experimental part of the lecture. From a very large number of experiments having no very clear connection, we have selected those which are either novel, or which may be said to be self-contained. Many of those who have watched Mr. Tesla's work would like to see him concentrate his energies on some definite object, experimental rather than speculative, and having a direct bearing either on the elucidation of some branch of electrical or electro-optical science, or some utilitarian application. When we heard that many of his new lamps were patented, we expected that he would undertake an Edison-like investigation and produce some useful result. On the other hand, he might have turned off on the purely scientific lines of Prof. J. J. Thomson, lines which, we should think, would be more agreeable to Mr. Nikola Tesla than mere inventing. If a few quantitative determinations of current, voltage, or even of frequency, had been given in the lecture, it would have had a definite

Digitized by Google

scientific value. To reduce even one out of the fifty experiments to a complete research, would be worth all the other forty-nine brilliant and suggestive demonstrations.

Mr. J. Erskine Murray's letter on the electro-chemical equivalent of zinc, which will be found in our correspondence columns, serves as a useful warning to physicists against the acceptance, as trustworthy, of any materials decorated with the epithets "pure," "puriss." "chemically pure," "pure for analysis," and so forth, which are offered by dealers in chemicals and reagents. Commercially "pure" zinc is generally fairly free from arsenic, the substance most objectionable for its commonest use, viz., the evolution of arseniuretted hydrogen in toxicological analysis; but it is a great mistake to suppose that it approximates to Zn. Chemists are often careless or confiding enough to be satisfied with a label, or the statement of a price list, as a guarantee of purity, but physicists and electricians are still more liable to be deceived, as they rarely require reagents of approximately absolute purity, and are unaware of the nature of the besetting impurities of any particular element or compound, and of the means for their removal. In all chemico-physical researches, the investigator, whether chemist or physicist, should consult with a colleague trained in whichever of the two branches of science he feels himself to be less competent, and be guided by advice drawn from more intimate experience.

The method of correcting for the action of the electrolyte *per se* on the cathode, adopted by Mr. Murray, is a good one, and its principle quite defensible, if not perfectly sound. A suggestion that was recently made by Mr. Blount, in a contribution on the accuracy of the copper voltameter, viz., to conduct the electrolysis in a neutral atmosphere, appears applicable here. The gain in weight of a zinc plate in a neutral solution of zinc sulphate could hardly proceed in the absence of free oxygen, and the use of a boiled-out solution of zinc sulphate *in vacuo*, or in an atmosphere of nitrogen, should prevent it altogether. Operating thus, Mr. Murray would probably have obtained a result free from the error he mentions, and thus the ingenious mode of correction he actually adopted would have been rendered unnecessary. With regard to the relation of the atomic weights of copper and zinc, the Paper by Dr. Gladstone and Mr. Hibbert, referred to by Mr. Murray, gives the value 1·0322 for the ratio Zn : Cu, which, when considered in conjunction with value 63·6 for copper, gives Zn = 65·6, O being 16.

In another column Mr. E. T. Carter reviews the various methods of charging for a supply of electricity which the exigencies of the situation have forced upon our central-station concerns. He points out that, while few of these devices come up to the ideal of charging every consumer in exact accordance with the plant-outlay his particular installation involves, none of them tend to encourage a day-load, that much-to-be-desired consummation.

In connection with this same knotty question a lengthy discussion recently took place in the Brussels Town Council. At Brussels it is proposed to charge 10 centimes per 100 watt-hours (10d. per Board of Trade unit), with a minimum of 5 francs per lamp per annum. This 5 francs minimum, it was argued, would seriously deter people from adopting the electric light. It is sometimes said that all these tariff devices are the result of the over scientific training of the electrical engineer. Had that gentleman, however, an electrical counterpart of the gasometer, the householder would be very little troubled with "Manchester," "Brighton," "Leeds," or "Metropolitan" scales; but until some such apparatus has been evolved, it will be necessary to keep down, by some means or other, the number of "idle" lamps. As regards the Brussels minimum, the historic argument that "it is *such* a little one" may surely be urged. In London, with electricity at something over 7d. per unit, 7s. 6d. has been found to be about the average income per 8-c.p. lamp wired, so that, with electricity at 10d., a 5fr. minimum is a very modest one. A consumer need only burn each 8-c.p. lamp wired for 150 hours in the year in order to exceed it.

The town of Hanley, Staffordshire, is being supplied with an electric supply service by its own municipal authority, and Mr. Lobley, the borough engineer, has issued a Report upon the undertaking. Alternating currents, transformer sub-stations, and low-pressure distributing mains, are being used. The old fallacy that the weight of copper in the mains is inversely as the square of the voltage, is trotted out in this Report to show "the enormous amount of copper buried in mains" when low pressure is used. There was some foundation for this academical idea when transformers were fixed in each house, and those who use it are always careful to talk of the weight of copper, and not of the cost of the mains. But with alternate-current sub-stations the low-pressure mains are practically the same as in a continuous-current low-pressure system, the only difference being that it is generally more difficult to procure sites for sub-stations than to fix feeding points for feeders; feeders, moreover, will in some cases have to be run from the sub-stations. The only advantage of alternating currents will then be the facility they afford for erecting a station outside a town, where land is less valuable. But this means extra expense in mains.

In his report, Mr. Lobley discusses the comparative cost of gas and electricity for street lighting. He takes 40 glow lamps of 60 watts each, and estimates the total annual cost at £98 for 4,000 hours of lighting. This is made up of £30 for interest on first outlay, £12 for lamp renewals, and £6 for painting. The remainder works out at 1½d. per unit supplied. It is admitted that the present cost of gas for these 40 lamps is £120. We should be very much surprised if these can be replaced by electric lamps for less than £150 per annum, and we cannot see any advantage in such replacement. Street lighting by glow lamps seems at present to be a great waste of good current, and one which must necessarily load the station at its busiest time, even if it helps to fill up the midnight and early morning hours. Cheap lamps run at high efficiency may, perhaps, help to remove the great difference between the cost of lighting by arc and by glow lamps but the visits of the

Digitized by Google

lamp-renewer would have to be almost as frequent as those of the lamplighter. Mr. LOBLEY has a patent device for switching on glow lamps for street lighting, by means of electro-magnets in the street arc-lamp circuit, and good-naturedly reserves free use of his invention for Hanley.

Electric Lighthouses.—It is proposed to fit the lighthouse on the Old Head of Kinsale with an electric light.

Burnley.—There is every probability that the municipal central lighting station will be finished in a month's time.

Electric Traction at Hanover.—A Siemens and Halske 13 car electric line came into operation at Hanover last month.

Edinburgh.—Prof. Kennedy has been appointed engineer to the Corporation in connection with the electric light which the Council propose to introduce.

The Dutch Telegraph Department.—M. J. P. Havelaar has been appointed Director-General of the Netherlands Post and Telegraphs, in succession to the late M. Hofstede.

Cable Interruptions and Repair:—

	Date of Interruptions.	Date of Repair.
Santiago de Cuba-Mole St. Nicholas	April 20th	June 7th
*Paramaribo Cayenne	April 15th	—
*St Thomé-Loanda	May 30th	—

* Not yet repaired.

Electrical Coast Communications.—Sir Edward Birkbeck, Chairman of the National Lifeboat Institution, and a member of the Royal Commission on Coast Communications, has been inspecting the American and Canadian coast communication systems.

Blackburn.—The Local Government Board has given their consent to the borrowing of £50,000 for electric lighting purposes, and the Borough Engineer is to prepare specifications and working drawings to enable the Corporation to obtain tenders for carrying out the work.

Brighton.—An inquiry by Mr. Thomas Codrington, an inspector of the Local Government Board, was held at Brighton on Wednesday into an application of the Town Council for sanction to borrow £8,200 for purposes of electric lighting. There was no opposition.

Obituary.—The death is announced of Prof. Moses G. Farmer, co-inventor of the once well-known Wallace-Farmer dynamo, and for many years Professor of Electricity at the United States Torpedo Station, Newport, R.I. Prof. Farmer died at Chicago on the 25th ult. He was in his 73rd year.

Electrical Bills in Parliament.—The following Bills have passed through Committee in the Lords:—Electric Lighting Provisional Order (No. 1) Bill; Electric Lighting Provisional Orders (No. 3) Bill. In the Commons the City of London Electric Lighting Bill has been read a second time.

Electric Traction.—The two Houses of Parliament propose to nominate the following members to be the Joint Committee on the Electric Powers Protective Clauses:—Earl Rosse, Earl Russell, Viscount Cross, Lord Clifford of Chudleigh, Lord Ker (Marquess of Lothian), Mr. Brunner, Mr. Forwood, Mr. Molloy, Sir Bernhard Samuelson, Major Darwin.

Royal Institution.—At the general monthly meeting on Monday last the special thanks of the members of the Institution were returned for the following donations to the fund for the promotion of experimental research at low temperatures:—Messrs. Crossley Bros, £50; James Mansergh, Esq., £21; Sir Henry Doulton, £50; Captain A. Noble, £50.

Honours.—Amongst the recipients of "Birthday Honours" were Mr. Charles Todd, Postmaster-General and Superintendent of Telegraphs of South Australia; Mr. George Berkley, Past President of the Institution of Civil Engineers; and Mr. Francis John Stephens Hopwood, Assistant Secretary, Railway Department, Board of Trade, who have been made Knights of St. Michael and St. George.

Southport.—After a 4½ hours' sitting, the Town Council decided that the resolution, that an electric light plant should be put down in the town area, should be referred back to the Committee, with instructions to bring up a statement by the electrical engineer of the comparative cost, advantages, and disadvantages of lighting the town area from Crowlands and Eastbank-street respectively, having regard both to the capital and working expenses.

Leicester.—At an open-air meeting of the Leicester Ratepayers' and Property Owners' Protection Association, on Tuesday last, it was unanimously decided to emphatically protest against the proposal of the Corporation to borrow £50,000 for the purpose of establishing the electric light, the meeting being of opinion that it was inadvisable at the present time to add to the already heavy debt of the town, especially by works of a speculative character.

Sunderland.—A special meeting of the Electric Lighting Committee of the Sunderland Town Council was held last Friday, when a report was considered which had been prepared by Prof. A. B. W. Kennedy. Taking into consideration the low price of gas in Sunderland, Prof. Kennedy considers that not more than 6d. per unit could be charged, at which rate an income of £2,500 might be expected from 5,600 lamps. After carefully considering the report, the Committee decided to bring it before the next meeting of the Council, and to recommend that a new Provisional Order should be applied for.

Thunderstorms. Thunderstorms of considerable severity visited the north-east on Saturday and Sunday, and buildings were struck by lightning at Bainton, near Stamford, Ilkeston, and Kirkheaton, near Huddersfield. On Saturday afternoon a violent thunderstorm occurred at Keighley, and an isolated farmhouse on the highway between Keighley and Ilkley was struck by lightning and completely wrecked. The chimney was cut away; stones weighing over one hundredweight were sent in all directions over a distance of 20 yards. The house was set on fire, and the furniture destroyed. The occupants were seriously injured.

Terrestrial Magnetism.—In his report for the year 1892 the Astronomer Royal states that a record of the sun's surface has been secured on 220 days. The mean daily spotted area of the sun has been 1,230 in 1892, as against 100 in 1890 and 566 in 1891. With regard to the magnetic observations, the photographic registration of magnetic declination, horizontal force, and vertical force, and of earth currents, with the accompanying eye observations of declination, force, and dip, has been maintained. The period has been one of great magnetic activity. In the year 1892 there were 22 days of great magnetic disturbance, and 25 days of lesser disturbance. The growth of the Observatory buildings, involving the introduction of large masses of iron being likely to cause disturbing effects on the magnetic observations, the Astronomer Royal represents as desirable that an auxiliary magnetic station should be established in the neighbourhood, at a distance which would prevent such danger.

Telephonic Statistics.—The following comparative table will enable our readers to form a good idea of the relative development of telephony in the four leading capitals of Europe. The telephone total for London has been deduced from the latest subscribers' list available. It should be mentioned that the National Telephone Company has recently (see *The Electrician*, Vol. XXX., March 31st, p. 621) inaugurated a system of £10 and £12 rentals, applying only to districts outside the City, and to domestic communications:—

Town.	Population.	Telephone subscribers.	Subscribers per 1,000.	Annual rental.	System.
London..	4,250,000	6,834	1·6	£20	Single wire, overh'd. multiple exchanges.
Paris ...	2,400,000	9,653	4	£16	Double-wire, underg'nd, 12 exchanges.
Berlin ..	1,600,000	20,000	12·5	£7 10	Single-wire, overhead, 8 exchanges.
Vienna..	1,400,000	6,100	4·3	£8 8	Double-wire, underground, 1 exchange.

Indian Cable Repairing.—Mr. A. L. H. Palmer, Superintendent, Government Telegraph Department, Madras Division, has, says the *Indian Engineer* of April 22nd, just returned to Madras from a tour of inspection in the South. Telegraphic communication between India and Ceylon is established by two cables from Ramiaswaram, in India, to Talmanaar, in Ceylon, one of gutta-percha and the other of india-rubber. The first had

Digitized by Google

become absolutely useless, while the second, though workable, was not in perfect order. The defects in the cables were within ten miles of the Talmanaar end of the cable. The work of repairing these defects was carried out with the steam launch "Emily," from Colombo, but as this had no accommodation on board for officers or coolies, the latter had to be accommodated on rafts, and the working party had to return to the shore at night and recommence work every morning. Mr. Palmer was engaged on this work from March 17th to April 4th, and has received a telegram from the Director-General of Telegraphs recognising the difficulties which he has had to contend with, and congratulating him on the success of the operations.

Bradford.—The Gas and Electric Supply Committee of the Bradford Corporation had a two hours' sitting on Friday last to consider a scheme propounded by Mr. Shoolbred for improving and extending the electric light supply to the town. The Committee have already had under discussion a scheme devised by Mr. Baines, the resident engineer, by which he proposes to substitute the three-wire system for the two-wire system, and also to extend the electric light mains a considerable distance, the total cost of all the work being between £5,000 and £6,000. The scheme which Mr. Shoolbred laid before the Committee does not provide for an extension of the area to be lighted, but for the substitution of the five-wire system. The Committee, after hearing Mr. Shoolbred's explanation, debated as to which scheme should be adopted, but eventually decided to adjourn the matter, and leave to a sub-committee the responsibility of calling Lord Kelvin to advise the Committee as to what was best to be done. A strong minority of the Committee urged that the present works were ample for the needs of the borough for next winter, and that it would be best to await the experiment of the five-wire system at Manchester, and any further developments of electrical appliances before embarking on a further outlay.

An Electric Meter Disputed.—On Friday last, at Brighton, Mr. Joseph Hall was summoned, as secretary of the Mikado Creamery Company, King's-road, for non-payment of £20. 10s. 9d. for electricity supplied by the Corporation and for rent of meter. Mr. E. C. Baldwin proved delivery of demands of £14. 15s. 6d. for the quarter ending December 31st, and £5. 15s. 3d. for the quarter ending March 31st. The defendant disputed the amount in the December quarter as excessive. It was pointed out that by the Act the amount registered was conclusive evidence of the rate due, subject to application being made for the testing of the meter. Defendant said he was no party to the passing of the Act. The Stipendary said he had heard that objection before, but he was afraid it would not hold. He gave judgment for the plaintiff for the amount claimed. Subsequently the defendant returned and said the meter was changed in December, and the Stipendary consented to allow the whole matter to be reopened. Mr. Arthur Wright, manager of the Electricity Works, said in December the defendant's meter stopped, and was replaced by one of the Ferranti type. The Stipendary suggested that the charge for October and November might be agreed between the parties. The case was eventually adjourned for a week.

The Most Economical Age of Incandescent Lamps.—In closing the discussion on Carl Hering's Paper, "The Most Economical Age of Incandescent Lamps," recently read before the American Institute of Electrical Engineers, the Chairman made the following remarks:—"There is much food for thought in Mr. Hering's Paper, and his ideas, as elucidated by him, and by the members who have favoured us by discussion, are clearly of such practical importance that they merit the mature consideration of all who are interested in illumination by glow lamps, whether producers or consumers. While the idea of cutting short the life of an incandescent lamp is an absolutely new one to me, I have thought, while listening to the discussions, that it is one capable of much wider application than the Paper suggests; for example, to human beings who have outlived their usefulness, and whose life is devoted to making the lives of their fellow creatures miserable. My early years were embittered by an aged and crabbed male relative, and I think now, if I had had then the suggestions contained in Mr. Hering's Paper, I might have taken into consideration the circumstance that it was a waste of energy to keep him going, and that in the interests of law and order, seeing that he had reached that period which Mr. O'Keenan, impelled by the hereditary instincts of his race, calls the 'smashing point,' it was my duty to disconnect him."

Telephone Extensions in Manchester.—The *Manchester Guardian* states that the National Telephone Company has determined to reconstruct and rearrange an extensive portion of their Manchester system, and propose to lay underground cables in the central parts of the city if the consent of the Corporation can be obtained. Should the Company's suggestions be accepted, three-fourths of the wires which are at present overhead will be removed and placed underground. It is intended that the wires shall be enclosed in 3in. iron tubes, each tube to contain 100 lines. The proposal was first laid before the Council in October last. Since that time plans have been submitted of the projected underground work, and much correspondence has passed, but no agreement has yet been come to. On May 20th, the General Manager of the Company wrote to the Town Clerk pressing the matter upon the attention of the City Council, and stating: "I am sure you will appreciate the urgency of the question when I tell you that the Company have been compelled, in consequence of the rapid increase in the number of subscribers, to commence their works, which are estimated to cost upwards of £40,000, and in the course of a few weeks will have no option but to proceed overhead, after which any arrangements to place the wires underground would not be feasible." The Paving, Sewering, and Highways Committee, in whose hands the matter rests, have presented a report to the City Council, embodying the correspondence, and concluding as follows:—"Your Committee, in view of the discussions which have taken place in the City Council, and the desire expressed that the whole subject should be considered, deem it desirable that the Council should give such instructions to your Committee as to the course to be pursued in relation to this matter as upon consideration of the subject it may deem necessary."

Mr. Harness and the "British Medical Journal."—In November last the *British Medical Journal* published the following paragraph:—"We have good grounds for stating that *The Times* has recently refused a four-column advertisement from the Harness Electropathic Belt Establishment, of the value of £80, a course worthy of the high and honourable traditions of that journal." "This paragraph," says the *British Medical Journal*, "was, in fact, inserted in the *Journal* with the sole object of raising boldly between ourselves and Mr. Harness the question whether the business carried on by him was a legitimate and honest one, or the very reverse; and we were prepared, at any cost and trouble, to have this question fully and fairly tried by a jury, and to abide by their decision on the issue presented to them. Accordingly, on the action being commenced, we admitted that we had published the paragraph complained of, and justified what we had written. Our readers will perhaps not be altogether surprised to learn that Mr. Harness, after we put in our defence to his action, took no further steps in the matter. Determined to bring him to book, after waiting a reasonable time, we applied for an Order that Mr. Harness should be compelled either to go on or to discontinue this action, and an Order was accordingly made that unless he proceeded to give notice of trial and to enter his action for trial within twenty-one days, it should be dismissed with costs. After what we have already stated, our readers will doubtless anticipate the sequel. The twenty-one days elapsed. Mr. Harness abandoned his action, and the same was dismissed with costs, since paid by him. These costs, being what are termed party-and-party costs, necessarily do not represent the expenses which the Association has been put to in preparing to meet and justify the paragraph which Mr. Harness has allowed to go against him unrefuted. That, however, is a very small matter. The result of this abortive action is a convincing proof that Mr. Harness was not prepared to meet the charges brought against him by the *Journal* in open Court, and is conclusive that all we have said on the subject of Mr. Harness and his so-called electric belts has been fully justified."

ELECTROMAGNETIC THEORY.—LI.

BY OLIVER HEAVISIDE.

(Continued from page 98.)

§ 202. Let the parallel conducting tubes be of finite resistance. As a result, the external disturbance penetrates into them, and a waste of energy follows. As a further result, the external disturbance becomes modified. This occurs in a twofold manner. By cumulative action, the nature of a wave sent along the leads may be profoundly modified as it progresses. Besides this, there is what we may term a local modification, whereby the wave at any place is no longer strictly a plane wave. It is merely with this effect that we are now concerned. The departure from planarity requires a considerably modified and much more difficult theory, no longer expressible in terms of V and C simply, in order to take it into account. But in the construction of a practical theory, we take advantage of the fact that the departure from planarity is slight, to which we have already referred towards the end of § 199. A line of electric force does not now start quite perpendicularly from the positive lead and end similarly on the negative lead. It has a slight inclination to the perpendicular, and therefore curves out of the reference plane to a small extent. In the dielectric itself, this peculiarity is of little importance. But the slight amount of tangentiality of the electric force at the surface of the leads, which is conditioned thereby, is of controlling importance as regards the leads themselves, and eventually through them, to the waves in the dielectric, by attenuating and altering the shape of waves (considered axially), as just referred to. We should now consider what form is assumed by the second circuital law in terms of V and C, when we admit that there is tangential electric force on the surface of the leads, but on the assumption that the minor effects in the dielectric itself, which are associated with the presence of the tangential force, are of insensible influence.

We may still regard V as the transverse voltage in the reference plane. Whether we go straight across from the positive to the negative lead, keeping in the reference plane, or leave it slightly in order to precisely follow a line of force in estimating the voltage, is of no moment, because the results differ so slightly. The quantity C is subject to a similar slight difference, according to the way it is reckoned. We may, perhaps, most conveniently reckon it as the circuitation of the magnetic force round either lead upon its surface and in the reference plane, because this way gives the exact value of the conduction current in the lead. But the circuitation in other paths in the reference plane will not give precisely the same value now that the waves are not quite plane. This difference we also ignore in the practical theory. In truly plane waves the electric current in the dielectric is wholly transverse. There is now really an axial component as well, but being a minute fraction of the transverse current, it is ignored. In short, we have to make believe that the waves are planar when considering their propagation through the dielectric, whilst at the same time we take into account the departure from planarity in considering the influence of the leads and what occurs in them. It is unfortunate to have to refer to small corrections, as it confuses the statement of the vitally important matters. Let us, then, set them aside now.

Construct the second circuital equation in the manner followed in § 201, in elucidating the meaning of equation (6). Consider a rectangle consisting of two transverse sides in reference planes at unit distance apart, beginning upon the positive and ending upon the negative lead, and of two axial sides of unit length upon the leads themselves. Reckon up the voltage in this rectangle. The transverse sides give V and $V+dV/dx$. The axial sides give E_1 and E_2 say, if E_1 is the tangential component in the direction of increasing x of the electric force at the boundary of the positive tube, and E_2 the same on the negative tube, but reckoned the other way. The complete voltage is then

$$E_1+\left(V+\frac{dV}{dx}\right)+E_2-V,$$

or

$$\frac{dV}{dx}+E_1+E_2.$$

It is also equal to $-L\dot{C}$, as in § 101. (There is no magnetic conductance of the dielectric now.) So

$$-\frac{dV}{dx}=E_1+E_2+L\dot{C}, \quad . \quad . \quad . \quad (16)$$

is the form assumed by the second circuital law.

Observe that we have made no specification of the nature of the leads, so that the equation possesses a high degree of generality. As regards the first circuital law, that is unchanged, being expressed by (5) when the dielectric is non-conductive, and by (9) when conductive, since the minor changes alluded to as regards V and C are not significant.

Being general, the equation (16) needs to be specialised before it can be worked. If our electromagnetic variables are to continue to be V and C, we require to express E_1 and E_2 as functions of C. Fortunately this can be done, sometimes very simply, and at other times in a more complicated way. To take the simplest case, let the leads be tubes (or sheets) of so small depth that penetration is practically instantaneous as waves pass along them. Then E_1 is not only the boundary tangential electric force, but is also the axial electric force throughout the substance of the positive tube. Similarly as regards E_2 for the negative tube. It is true that, in virtue of the transverse electric current from tube to tube, there is also transverse current in the tubes, and, therefore, transverse electric force, but this is to be ignored, because it is a small fraction of the axial. The current density in the positive tube is therefore axial, of strength k_1E_1, if k_1 is the conductivity of the material; and the total current in the tube is K_1E_1, where K_1 is the axial conductance per unit length, or, which is the same, E_1R_1, if R_1 is the resistance per unit length. But this quantity is also the previously investigated quantity C, the circuitation of the magnetic force on the boundary of the tube. So we have the elementary relations

$$E_1=R_1C_1, \qquad E_2=R_2C_2, \quad . \quad . \quad . \quad (17)$$

which are, be it observed, essentially the connections of the electric and magnetic forces at the boundaries, though brought to a particularly simple form by the instantaneous penetration. The second circuital equation (16) therefore takes the form

$$-\frac{dV}{dx}=(R_1+R_2)C+L\dot{C}. \quad . \quad . \quad . \quad . \quad (18)$$

Or, finally, if R is the resistance per unit length of the two leads,

$$-\frac{dV}{dx}=RC+L\dot{C}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (19)$$

which is the practical equation for most purposes. Observe, comparing it with (12), that there is an identity of form, but with a changed meaning of the symbol R. In the exactly stated problem of plane waves running through a medium of duplex conductivity bounded by perfect conductors, the quantity R is the transverse magnetic conductance per unit length axially. In the present approximately stated problem of very nearly plane waves running through an electrically conducting medium bounded by resisting wires, the quantity R is the resistance of the wires, per unit length axially. What we have to do, therefore, in order to turn the real problem into one relating to strictly plane waves admitting of rigorous treatment, is to abolish the resistance of the leads and substitute equivalent magnetic conductance in the dielectric medium outside. The two materially different properties are nearly equivalent in their effects. Equations (13), (14), (15), still hold good, only RC^2 is now to be the rate of waste in the leads, instead of in the medium generally due to the (now suppressed) magnetic conductance. The flux of energy is now not quite parallel to the leads everywhere, but has a slight slant towards them. But the usual formula gives the waste correctly. The product E_1H_1 of the tangential electric force E_1 and the magnetic force, say H_1, at the boundary of the positive lead, is the rate of supply of energy to the lead per unit surface. Therefore, by circuitation, the product E_1C is the rate of supply per unit length axially. This is the same as the previous R_1C^2.

The equivalence of effect of magnetic conductance externally and of electric resistance in the leads, is undoubtedly a somewhat mysterious matter, principally because it is hard to see (apart from the mathematics) why it should be so. As regards

Digitized by Google

the above reasoning, however, it is essentially simple, and is a direct application of fundamental electrical principles. It may, therefore, cause no misgivings, except the doubt that may present itself whether the ignored small effects in the dielectric due to departure from planarity of the waves are really ignorable. As a matter of fact, they are not always of insensible effect, and plenty of problems can be made up and worked out concerning tubes and wires which do not admit of the comparatively simple treatment permissible when V and C are the variables, and the results are exceedingly curious and interesting, though quite unlike those at present in question. But these are not practical problems, and have little bearing upon the question of the free propagation of waves along long parallel straight wires. They do not start as full grown plane waves from the source of disturbance, but they very soon fit themselves on to the wires properly, and then follow the laws of plane waves pretty closely.

Although thin tubes for leads were specially mentioned in connection with equation (19), yet any sort of leads will do provided the penetration be sufficiently rapid to be instantaneous "within the meaning of the Act." It is obviously true for steady currents, when the inertial term disappears and R is the steady resistance. And if the variations of current be not sufficiently rapid to cause a sensible departure from uniformity of distribution of current in the conducting wires, then, of course, (19) may still be safely used. At the same time, it should be mentioned that the inductance L should, under the circumstances, be increased by a (usually) small amount due to induction in the conductors themselves, as will be presently noted more closely. Furthermore, remember that no allowance has been made for the influence of parallel conductors, should there be any. The earth does not count if the leads be alike and equidistant from the ground, as its influence can be embodied in the values of L and S, the inductance and permittance.

§ 203. The next question is what to do when penetration is not instantaneous within the meaning of the act. We should first go back to (16), which remains valid, and inquire whether the tangential electric forces cannot be expressed in terms of the current (or conversely) in some other way than by a linear relation. Suppose we say

$$E_1 = R''_1 C, \qquad E_2 = R''_2 C. \quad . \quad . \quad . \quad (20)$$

Is it possible to give a definite meaning to the symbol R″? Is there a definite connection between C, regarded as a function of the time, and E_1 or E_2 also regarded in this way?

Imagine a wire to be free from current, and, therefore, electrically neutral. Now expose its boundary to tangential electric force, beginning at a certain moment, varying in some particular way with the time later, and then ceasing. The result is that C, the total current in the wire, will run through a particular sequence of values, and then finally cease. If we begin again with the applied force, and make it run through the same values in the same manner, we shall again obtain the same values of C at corresponding moments. So far, then, the connection is a definite one. Moreover, if we make the applied force run through the same values increased in a certain ratio, the same for all, then the current will have its previous values increased in the same ratio. But if we change the nature of the applied force as a function of the time (irrespective of size) we shall find that C is not merely changed as a function of the time, but also as a function of the applied force. That is, the mere value of one does not necessitate any particular simultaneous value of the other. So, if we keep to the usual sense meant when algebraists say $u = f(x)$, or u is a function of x, we cannot say that C is a function of E. It is, nevertheless, true that the march of C is strictly connected with that of E, so that when the latter is given, the former is obligatory. To deny this would be equivalent to the denial of there being definite controlling laws in operation. The full connection between E and C, however, involves not merely their values, but also the values of their first, second, third, &c., differential coefficients up to any order. That is, the symbol R″, taken by itself, is a function of the differentiator d/dt. To illustrate by a simple example, suppose

$$R'' = R + Lp + (Sp)^{-1}, \quad . \quad . \quad . \quad . \quad (21)$$

where R, L, S are constants, and p stands for the differentiator. This means that

$$E = \{R + Lp + (Sp)^{-1}\}C, \quad . \quad . \quad . \quad . \quad (22)$$

or

$$E = RC + L\dot{C} + S\int C dt, \quad . \quad . \quad . \quad . \quad (23)$$

in the common notation of integrals. Now imagine the march of C to be given. This implies that the march of $\dot{C}$ is also known, and likewise that of $\int C dt$. Consequently the march of E is explicitly known. It is less obvious that when the march of E is given, that of C is known, by the same operator implicitly. That is, by (22) we have

$$C = \frac{E}{R + Lp + (Sp)^{-1}}, \quad . \quad . \quad . \quad . \quad (24)$$

and given E as a function of the time, C is known as a function of the time, or if not known, can be found without ambiguity. It is not obvious, because we do not immediately see how the operation indicated in (24) is to be carried out, whereas, in the case of (22), it is visible by inspection. Nevertheless, the fact that the march of E, physically considered, conditions that of C, makes the above equation (24) not only definite, but complete. In the usual treatment of the theory of differential equations, there is no such definiteness. Arbitrary constants are brought in to any extent, to be afterwards got rid of. Now this is all very well in the general theory of differential equations, where arbitrary constants form a part of the theory itself, but for the practical purpose of representing and obtaining solutions of physical problems, the use of such arbitrary and roundabout methods (which are too often followed, especially by elementary writers) leads to a large amount of unnecessary work, tending to obscure the subject, without helping one on. It would not, perhaps, be going too far to say that such a misuse or inefficient application of analysis often makes rigmarole.

When we say that $E = R''C$, where R″ is the resistance operator (so called because it reduces to the resistance in steady states), we assert a definite connection between E and C, so that when C is fully given as a function of the time, and the operations contained in R″ are performed upon it, the function E results, and similarly, when it is E that is given, then the inverse operator $(R'')^{-1}$ (or the conductance operator) acting upon it will produce C. There may be an infinite number of differentiators in R″, as p, p^2, p^3, and so on, where p^n means d^n/dt^n. But there is not a single arbitrary constant involved in $E = R''C$, nor, indeed, anything arbitrary.

Returning to the wires, the form of the resistance operator, as a function of p, depends upon the electrical and geometrical data. It has been determined for round wires and round tubes, and plane sheets. We may take

$$-\frac{dV}{dx} = (R''_1 + R''_2)C + L\dot{C}, \quad . \quad . \quad . \quad (25)$$

as the form of the second circuital law, and make the determination of the operators a matter of separate calculation.

As already mentioned, when C is steady, R''_1 degenerates to R_1 and R''_2 to R_2, the steady resistances (per unit length) of the wires, tubes, rods, or cylinders of any shape that may be employed. At the same time the inertial term disappears. Also, when C varies, it is sometimes sufficient to take into account only the first approximation to the form of the operators. This is, for a solid round wire,

$$R''_1 = R_1 + \tfrac{1}{2}\mu_1 p, \quad . \quad . \quad . \quad . \quad . \quad . \quad (26)$$

and similarly for R''_2. This $\frac{1}{2}\mu_1$ is the value of the steady inductance of the wire, μ_1 being its inductivity. When not solid, or not round, some other expression is required. Notice that this brings (25) to the elementary form (19), because the inductance of the wires may be included in L itself, which then becomes the complete steady inductance (per unit length axially), including that due to the dielectric and that due to the two wires. This usually means only a small increase in the value of L, unless the wires be of iron.

But besides the above simplification, there is an exceedingly important general case in which a similar reduction takes place. This occurs when the sources of disturbance vary simple periodi-

Digitized by Google

cally with the time. Then the electric and magnetic fluxes everywhere vary ultimately according to the same law with the same period, provided the relations of the fluxes to the forces are linear; that is, when the conductivity, permittivity, and inductivity, are constants at any one place. Now, when this comes to pass, both E and C in the equation $E = R''C$ vary simple periodically with the time. But when the sine or cosine is differentiated twice, the result is the same function negatived, and with a factor introduced. Thus, if the frequency is $n/2\pi$, so that $\sin(nt+\theta)$ may be considered to be the time-factor in the expression for either E or C, we have the property $d^2/dt^2 = -n^2$. Put, therefore $p^2 = -n^2$ in the expression for the resistance operators, and we reduce them to

$$R''_1 = R'_1 + L'_1 p, \qquad R''_2 = R'_2 + L'_2 p, \quad . \quad . \quad (27)$$

where R' and L' are functions of n^2. They are, therefore, constants at a given frequency, and this is a very valuable property, as it is clear at once that we reduce the equation (25) to the simple form—

$$-\frac{dV}{dx} = (R'_1 + R'_2)\,C + (L + L'_1 + L'_2)\,pC \quad . \quad (28)$$

or, more briefly and clearly,

$$-\frac{dV}{dx} = R'C + L'\dot{C}, \quad . \quad . \quad . \quad . \quad (29)$$

which is the same as (19), valid when the penetration is instantaneous, but with different values of the constants involved. The steady resistance R is replaced by R', the effective resistance (of both tubes per unit length) at the given frequency, and L the steady inductance (inclusive of the parts due to the wires) by L', the effective inductance.

Owing to the reduction of the second circuital equation to the primitive form, we are enabled to express the propagation of simply periodic waves along wires by the same formulæ, whether there be or be not imperfect penetration. We simply employ changed values of the constants, resistance and inductance, which may be independently calculated, or left to the imagination, should the calculation be impracticable. This is, when it can be effected, the best way of making extensions of theory. Do the work in such a way that harmony is produced with the more rudimentary results, and so that they will work together well, and the new appear as natural extensions of the old. An appearance of far greater originality may, indeed, be produced by ignoring the form of the elementary results, but the results would be cumbrous, hard to understand, and unpractical.

The effect of increasing the frequency from zero to a high degree is to first lessen the penetration, and end in mere skin penetration. Consequently, the quantity L', the effective inductance, goes from the full steady value $L + L'_1 + L'_2$, and finishes at L simply, the inductance of the dielectric. But the difference need not be great. In the case of suspended copper telephone wires the inductance of the dielectric is far larger than the rest, so that there is no important variation in the value of the inductance possible, nor would there be were the frequency increased up to that of Hertzian vibrations. But as regards the effective resistance, the case is different. As the distribution of current in a wire changes from that appropriate to the steady state, the resistance increases, and the increase is not always a negligible matter. If long-distance telephony were carried on along iron wires it would be a very important effect. But the Americans, who were the introducers of long-distance telephony, soon found that iron would not do, and that copper would. The reason of the failure is mainly the largely increased resistance of iron. In copper, on the other hand, it is an insensible effect at the lower limit of telephonic frequency of current waves, with the size of wire employed, and is not very important at a frequency three or four times as great. On the other hand, in the numerous experiments with very rapid vibrations of recent years, due to Hertz, Lodge, Tesla, and many others, the increased resistance due to imperfect penetration becomes a very important matter, and is one of the controlling factors that should be constantly borne in mind.

(To be continued.)

THE PRICE OF ELECTRIC SUPPLY.

BY E. TREMLETT CARTER.

In his Presidential Address, before the Junior Engineering Society, on November 4, 1892 (see *The Electrician*, Vol. XXX., page 29), Dr. Hopkinson laid down the principle that "the charge for a service rendered should bear some relation to the cost of rendering it," and showed that the cost of rendering to the public the service of electric supply might be expressed in an equation containing one large *constant* term and one term depending on the amount of energy supplied. As a matter of fact, the cost of producing energy at a station takes the mathematical form—$C = K + k\,Q^n$); where K represents the fixed costs, Q the output, and n is an exponent always less than unity. If the variable charges were simply proportional to the output, n would be unity; but, as a matter of experience, the efficiency of a station falls with the output, owing to the increased consumption of fuel at lower rates of supply. In condensing stations, with a largely sub-divided plant, n would be nearly unity and k would be small; while, with large non-condensing or triple-expansion engines, k would be very much larger, and n would be of the order of 0·5. If we divide C by the output Q, we obtain c, the cost of unit output, and

$$c = \frac{K}{Q} + k\,(Q^{n-1})$$

Thus, if the output of the station is very small, the cost of producing the unit of energy per hour will be enormous; and the curves representing the relation between the costs at different outputs and at different types of stations, will be a series of hyperbolæ, but having different sets of axes. For example, the rectangular hyperbola of the simplest form will occur where n is unity, and will have an asymptote or abscissa k units of length above the zero line of the curve. In all cases the cost, c, will indefinitely approach infinity as the output approaches zero.

In the majority of cases the exponent of efficient generation, n, is practically an indeterminate quantity; but station engineers like to be able to believe that its value lies near enough to unity for the difference to be negligible. At any rate, for simplicity's sake, it will be well to assume that its value is practically unity. The cost of supplying any number of units of energy to a consumer, in any given time, will then become

$$C_1 = K_1 + k\,U$$

where U is the number of units supplied; and K_1 is a constant for fixed charges, depending on the amount of plant involved, and directly proportional to the number of lamps of any given size, and the cost per unit will be

$$c_1 = \frac{K_1}{U} + k.$$

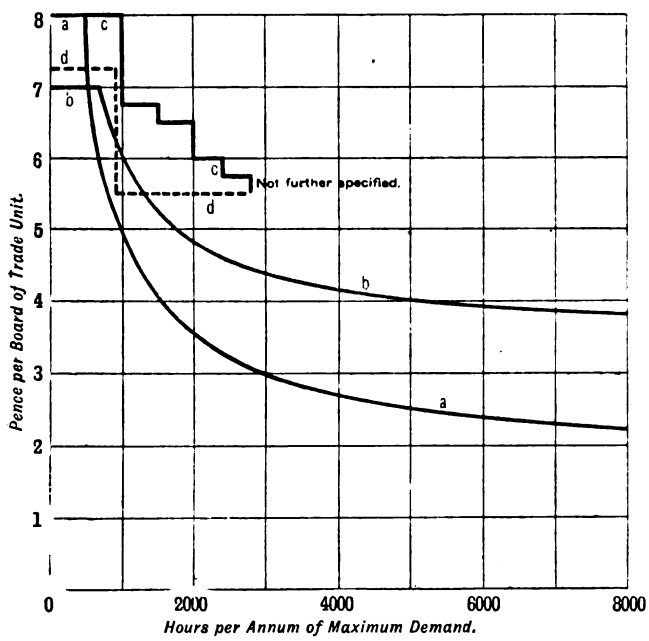
Experience shows that the second or constant term is always smaller than the first or variable term; or, in other words, that there is a rapid rate of decrease in the cost of supplying a unit of energy in proportion as the number of units supplied increases, the supply taking place in any given unit of time. The effect is analogous to the well-known market law—"a reduction on taking a quantity."

This being the state of affairs, electrical engineers who have the management of central-station business have considered whether it would not be advisable to adopt a scale of charges which should run parallel to the curve of costs. The consumer who puts 100 lamps on to his wires, but never uses more than 10 at a time, does not compare favourably with the man who, having 10 lights, uses all of them very frequently. The constants of their two equations are not the same. The former requires the supply undertakers to be ready at any time to supply current for 100 lamps, but never pays for more than 10; so that the undertakers are involved in a high rate of fixed cost, K_1, in his case. The other consumer, having one-tenth of the plant installed, has only one-tenth of the constant for fixed charges; he therefore costs the undertakers less for every unit he consumes in the given period. It is important to notice that *the cost of supply does not so much depend on the maximum number of lamps used in the stated*

Digitized by Google

period as on the maximum number which might be used, together with the number of units of energy actually consumed. For the amount of plant which the supply undertakers must hold in readiness against any given house circuit depends only on the number of lamps which can be used on that circuit. It may happen that a whole year may pass before they *are* all used, and during that entire year the fraction of the generating plant which they represent will to a great extent have been unpaid for, unless the charges are based upon the total number of lamps wired. We are not now concerned with the policy of adopting such a scale of charges, but merely with the fact that, for the charges to be parallel with the costs, such a scale is necessary.

The system of charging for energy, proposed by Dr. Hopkinson, and known as the "Manchester" system, is one which approximately follows the scientific lines referred to in the foregoing paragraph. It arranges that "for each unit per hour in the maximum power demanded, a charge not exceeding £3 per quarter, and in addition for each unit supplied, a charge not exceeding twopence," shall be made. If the maximum power demanded is based upon the total number of lamps wired, the system becomes perfectly scientific; but it is contended that this would introduce objectionable features, as will presently be seen. As a matter of fact, it has been proposed to employ a



(*a.*) Manchester. (*b.*) Brighton. (*c.*) Leeds. (*d.*) Metropolitan Co.

maximum recording ammeter, by means of which the maximum demand during the quarter can be determined. In the accompanying diagram it will be seen that the charges on the "Manchester" system (curve *a*) represent 8d. per unit if the supply is taken for less than 500 hours per annum. In other words, if the lamp-hourage is not equivalent to more than the maximum demand lasting 500 hours this full charge will be made. To obtain energy at 4d. per unit the maximum demanded supply must be kept up for 1,500 hours, or there must be an equivalent consumption. Thus, suppose the maximum demand to be 100 lamps, then there must be at least 150,000 lamp-hours used in the year. This is equivalent to running the full demanded current through the circuit from dusk till about 10 p.m. every day in the year.

The "Brighton" system, introduced by Mr. Arthur Wright, is one which possesses many interesting features, and nearly the same defects as the system we have just considered. This method of charging is now in use at the supply station of the Brighton Corporation. It is designed as follows:—A charge of 7d. per unit demanded for the first two hours every day, and 3½d. for each additional unit consumed. The maximum number of units demanded is obtained by means of a maximum recording ammeter, the readings of which are taken during the three darkest months in each half-year. The average of the readings in any one half-year is considered to be the maximum demand. Thus, if P is the maximum demanded power in kilowatts, and U is the number of units consumed in the average twenty-four hours (as determined by the meter), then the daily duration of the maximum demand is U/P. The excess of this over two hours gives the time during which the lower scale of charges is being made. For example, if U is twice P, there is no excess, and the full charge will be made for every unit; if U is 2·8 P, the price of each unit throughout becomes 6d.; while, to bring the price down to 4d. per unit, the maximum demand must be kept up for fourteen hours per day. Finally, if the maximum demand is maintained continuously during the whole of every day (twenty-four hours), the price of each unit consumed reaches its lowest limit of 3·83d. A comparison of this system with the "Manchester" system may be made by comparing curves *b* with *a*. In curve *b* the "Brighton" system has been reduced to the same scale of measurement as in *a*, namely, the number of hours in the year during which the maximum demand is used and the price per unit for abscissæ and ordinates respectively.

Now as to the defects of these two systems. The most obvious fault in them is the fact that they do not really charge the consumer for what he may at any moment demand; they merely charge according to what he may have demanded in the particular quarter or half-year in which the bill is drawn up. For example, suppose two separate consumers have, the one 1,000 lamps and the other 100; and that they both manage to keep the maximum number of lights on at any one time as low as 50. Let us further suppose that each of these consumers takes exactly the same number of units through the meter in the stated time. Then, on either of these systems, each of the two consumers would have to pay exactly the same amount of money. Obviously, this is not what the financial conditions require. The larger householder is a greater burden to the supply undertakers; for he may, at any time, put the whole of his lights on the circuit. Not till he does so, however, will he pay a penny for the privilege of having them wired. It has been urged that to estimate the maximum demand on the basis of the number of lamps wired would discourage the wiring of occasional and unimportant lamps; while these are often of great service to the supply undertakers, because they are most frequently used at times when other lamps are not in use. Another defect lies in the fact that if the consumer gives two big parties in one quarter or half-year, and none at all in the next, he does not pay so heavily as if he gives a party in each separate period; while he is equally a burden on the station in the former as in the latter case. A last defect is that neither of these systems encourages the consumer to take his energy at a time when the supply people would prefer that he should do so. This last requirement arises from the fact of the exponent not being exactly unity; in other words, it is due to the fact that the supply people can afford to pay something to encourage a consumer to take current when their station is running at a low load. Now, neither of these systems offer energy at a cheaper rate during the hours when the station can spare it better than during the few hours when it is pressed with customers. It is true that they induce the customer to stay a long while on the mains, but they do not induce him to put his load by preference on the mains during daylight hours rather than during hours from dusk till 8 or 9 p.m.

Such an inducement is offered by the method of differential charges in use on the St. Pancras mains. From this station, energy can be obtained for 3d. per unit for power alone, but for not less than 6d. per unit for power and light or for light alone. In the daytime, therefore, energy will cost only 3d.; while at night, unless it be used for power alone, it will cost 6d. This is effected by providing the power-and-light customer with a two-way switch, by means of which he may put on the current through his motor alone at the lower price, the current passing through one meter; or he may send the current through another meter to the lamps and motor, or the lamps alone. The chief defect of this system is that it encourages the consumer of electricity for large amounts of motive power to burn gas instead of electric light, if he desires to do work in the night; for, if he puts in electric light, he will pay for all the night work at the higher rate.

Digitized by Google

In addition to these systems, it has been proposed to employ meters which shall be automatically switched on to a different rate of indication at different times of the day. Mr. Kapp proposes to have a clock which should shunt a varying fraction of the current through the meter, a large fraction going through when a high rate of charge is to be made, and a less fraction when energy can be supplied cheaper. Others have proposed to graduate the meter to register, not electricity, but £. s. d. on a variable rate of charging. The defects in these systems arise from the uncertainty of the mechanism and the impossibility of calibrating it. The machinery of the "Leeds" system of charging is entirely financial. In this system, the customer is granted a rebate on the principle of trade discounts. He is expected to declare what maximum supply he will require, and will be charged according to the following plan :—The full price of 8d. for the maximum supply extending over less than 250 hours ; 10 per cent. discount on the full price if the consumption reaches 250 hours, 15 per cent. if it reaches 375 hours, and so on. The number of hours is reckoned per quarter, so that a large consumption of energy per lamp is expected before any rebate is granted. Curve *c* shows the scale of charges on the "Leeds" system. It may be remarked that the proposal to limit the consumer to the actual maximum supply demanded, by putting into his main fuses of such a size that fusion will take place if he exceeds it, is one which cannot be tolerated. Such a system takes no account of the necessary factor of safety for fuses, and would bring the fuses to the very point of melting at each time that the maximum demanded supply was being taken. Another defect in the "Leeds" system is the lengthy period over which the lamps must be used before any rebate is given, the full price being charged unless the consumption exceeds 1,000 hours per annum, or nearly three hours per day. Business houses using the light on six days in the week, would require to burn the maximum number from sunset till a quarter-past nine every evening to get the 10 per cent. rebate ; and till half-past 12 a.m. to get the 20 per cent. rebate. Most shops, many private houses, and all churches, would be excluded from any discount whatever ; and being charged a very high rate for supply, would be induced to adopt gas or some other illuminant. If the "Leeds" system were based upon the number of lamps wired, and the periods before the successive discounts come into operation were shortened, it would constitute one which would have the great merit of treating small consumers on as favourable a footing as large ones. Apart from this, however, it possesses all the defects of the "Brighton" and "Manchester" systems. The scale of charges adopted by the Metropolitan Electric Supply Company is based upon the total number of lamps *wired*, the customer being charged at a rate which depends upon the quarterly consumption *per lamp on his circuit*. The details of the method are : A price of 7¼d. is charged for all supply up to 8 units per quarter per 35-watt lamp wired, and the lesser price of 5½d. is charged for each additional unit. Collating this with the other scales, at so much per annum, we arrive at curve *d*. Up to 32 units per annum per lamp the price is 7¼d. per unit, or £1 per lamp ; and this requires each lamp to be run for about 900 hours per annum, or three hours per working day. Every lamp must, therefore, be alight from dusk till 9 p.m. throughout the year before the lower tariff is reached. The direct effect of this will be to eliminate unnecessary, or hardly necessary, lamps, as will be seen by the following comparison between two circuits :— In the first circuit let there be 20 lamps, which will all be used nightly from dusk till midnight ; in the second circuit let there be 20 lamps as above, and 10 lamps which are only turned on for an average of a minute or two per diem. What are the respective annual bills for these circuits ? That for the first will be £1. 15s. 6d. per lamp, or £35. 10s. for the set ; the second bill will be £1. 8s. per lamp, or £42 for the set of 30 lamps. The 10 idle lamps together cost £6. 10s., or, separately, about 13s. per annum, for the privilege of having them wired. This system favours the small consumer, in so far as he is (electrically) an industrious one, but the tariff is not so attractive to the general consumer as that offered either at Manchester or at Brighton.

The objection has been raised to the method of charging according to the number of lamps *wired*, that the consumer can easily substitute 16 c.p. or even higher-power lamps for 8's. As a matter of fact, however, this constitutes no obstacle in the way of adopting this system. The addition of a maximum recording ammeter is all that is necessary. Suppose a consumer puts in 100 lamps of 8 c.p. Let him be charged on the basis of this number of lamps, *as long as the current he uses does not exceed that required for this number of lamps*. And, if he chooses to substitute 16-c.p. lamps for the 8's, then, as long as he never takes more current than would be required for the 100 former sized lamps, he does the supply undertakers no injury. On the other hand, if he puts into circuit so many 16's that more current than the 100 8's is taken, the recording ammeter will tell its little story. If he did that, the recorded current on the instrument might be made the basis of charge ; or, better still, to act as a deterrent, he might be charged the full 8d. a unit for every unit passed through his meter. If consumers understood that this would be done, they would not put larger lamps in place of small ones. As regards the inducements which should be offered to consumers to fill up the day load, which is a very much more serious matter, we would suggest the following plan. Let every consumer whose consumption is so large that he can afford to pay a little higher rental for the meter, if thereby he can get energy during the day at a cheap rate, be provided with a single meter of the following description :—The meter will be of the ordinary type, except in so far that it will be provided with two sets of counting wheels and dials. One set will register energy during the day, and the other set during the night, both being actuated by the same mechanism. At times, which shall be determined upon by the supply undertakers, the one set will be automatically disconnected from the gearing, and will be locked ; at the same time the other set of counting wheels will be thrown into gear. Mechanism for doing this would be very simple, and not likely to get out of order. In order to determine with great accuracy the successive periods during which the sets would be alternately in gear, a clock, provided with a simple electro-motor and set of contacts, would be necessary. This clock might be automatically wound up by means of the motor, or it might be kept in synchronism with a station clock, and would thus supply the customers with Greenwich time. The function of the motor would be to throw over the couplings for the sets of counting wheels from time to time. In addition, a simple galvanoscope in the front of the meter might be made to indicate whether the higher or lower rate of charge was being made, by pointing to the right or to the left. The entire additional mechanism would not cost more than would be covered by an additional few shillings on the annual meter rental ; and, though it would not pay the small consumer of lamps, it would undoubtedly furnish an attractive tariff to the large consumer of lamp and motor-power.

BOOK RECEIVED.

"Summary of the Factory and Workshop Acts." By Emile Garcke and J. M. Fells. (London : Crosby Lockwood and Co.) Price 6d.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, June 9th.

PHYSICAL SOCIETY.

5 p.m. Papers to be read : (1) "A New Photometer," by A. P. Trotter ; (2) "Notes on Photometry," by Prof. S. P. Thompson, F.R.S. ; (3) "The Magnetic Field Near a Wire," by Prof. M. Minchin, M.A.

ROYAL INSTITUTION.

9 p.m. Evening Discourse : "The Recent Solar Eclipse," by Prof. T. E. Thorpe, F.R.S.

THURSDAY, June 15th.

CHEMICAL SOCIETY.

8 p.m. Papers to be read.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

STEEL-PLATE PORTRAITS

Of Willoughby Smith; W. H. Preece, F.R.S. (President of the Institution of Electrical Engineers); Michael Faraday; Sir John Pender, G.C.M.G., M.P.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Patey, C.B.; Dr. John Hopkinson, F.R.S.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz; Prof. W. E. Ayrton; Lord Rayleigh, F.R.S.; Cyrus W. Field; Werner von Siemens; and Sir James Anderson, have been issued as Supplements to "THE ELECTRICIAN."

Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price 4s. 6d., carriage paid (U.K.).

NOW READY.

Volume XXX. of "THE ELECTRICIAN," price 12/6; post free, 13/6; abroad carriage extra.

Cases for binding Volume XXX., price 2/0, post free, 2/3.

The Publisher is able to supply a set of the Volumes of "THE ELECTRICIAN" complete except for three Nos. Price on application.

ELECTROSTATIC VOLTMETERS.

It is tolerably safe to say that COULOMB made the first electrostatic voltmeter, as distinguished from the electroscopes of gold leaf and of pith balls. In making this statement we, at all events, run no risk of an indignant letter from a prior inventor. For laboratory work the quadrant electrometer and the highly-developed guard-ring electrometers of Lord KELVIN have satisfied all requirements, and multicellular and other forms have been offered for commercial use. Mr. A. WRIGHT, of Brighton, was one of the first, if not the very first, to use an electrostatic direct-reading voltmeter for daily use in the engine room of a central station. This he did some six years ago, and his instrument was described in *The Electrician*, Vol. XX., p. 153. There was no distinct demand for electrostatic voltmeters until the high voltages of alternate-current supply became general. Excellent electro-magnetic voltmeters had by this time been so designed that temperature errors were eliminated, and unlike the early voltmeters they could be left always in circuit. The Cardew voltmeter had also arrived at a high degree of accuracy, but for measuring 1,000 or 2,000 volts it was necessary either to use a transformer to bring down the pressure to 100 volts or so, or to put a large resistance in series. Little transformers are troublesome to make and likely to break down, and their transforming ratio cannot be relied upon, whilst the large resistance plan entails a great expenditure of power. A Cardew voltmeter, with the necessary resistance, takes 1 H.P. at 2,200 volts. Mr. SWINBURNE pointed out in his Paper on "Electrical Measuring Instruments," read before

Digitized by Google

the Institution of Civil Engineers last year, that each watt lost in an instrument constantly in use was equivalent to the interest on £1. Messrs. Swinburne and Co. were one of the first to offer substantial and accurate electrostatic voltmeters, some with suspension for laboratory work, and others constructed in a style suitable for the requirements of the switch-board of a central station. Four Swinburne electrostatic voltmeters of the laboratory type were used by Dr. Fleming in his recent exhaustive researches on transformers, and he found no difficulty in reading to about one-quarter per cent., a difference of three or four volts in 2,400 being easily detected. The only defect pointed out by Dr. Fleming was the large moment of inertia of the needles and the absence of a suitable damping arrangement. On December 2, 1892, during the discussion on Dr. Fleming's Paper, we published a brief account of recent improvements which had been made in these instruments. An oil damper had been added, and it was claimed that with a steady pressure the instrument might be read to half a volt in 2,000.

The quadrant electrometer, from which most electrostatic voltmeters have been developed, was provided with a "needle" having a considerable moment of inertia. In constructing a sensitive instrument, under conditions which preclude the use of fine suspension fibres, the use of a large "needle" introduces difficulties. Lord Kelvin has met this in his multicellular voltmeter by the use of a number of small needles, and Prof. Ayrton and Mr. Mather have abandoned the flat form, and have used curved plates, giving a large surface, but keeping down the moment of inertia. The working parts of the instrument, which we briefly describe in another column, has a curious but accidental resemblance to those of the Hartmann and Braun electromagnetic instruments, which are mere modifications of the well-known Evershed gravity instruments. As in the Evershed instrument, by different shaping of the parts, any desired arrangement of scale may be obtained. For laboratory work "dead-beatness" is very desirable, if only for saving time, but it is by no means so important for switch-board work. "Dead-beatness" is an awkward term, and to say that one instrument is "rather dead-beat," and that another is "very dead-beat" shows a ridiculous poverty of language. The literal equivalent "thanatotyptic" does not help us much. Fortunately there is but little need for it. What is meant by a very dead-beat instrument is that it is well damped. If it is so well damped that the index does not overshoot the mark it is said to be aperiodic. The term "dead-beat" is often used as if it had something to do with a slow period. It would be better to restrict it to mean that a short space of time elapses between the starting of the index, say, from zero, and its final arrival at its destination. For switch-board use a slow period is rather an advantage, and the expanding of the scale at the working part should receive more attention than has been given to it. For laboratory purposes a more or less evenly divided scale may be useful, but to use such a scale for a switchboard, if an expanded scale is possible, is to make a large sacrifice in sensitiveness.

Electrostatic instruments perhaps fail to inspire such confidence as has been placed, and too often misplaced, in electromagnetic instruments. In the latter, two or three hundred ampere-turns are fixed once and for all to give the directive force, and gravity or a spring gives the control. The coils are not likely to alter, and the iron cores or armatures, though they are to blame for most of the errors, can only be injured in so far as they may become displaced with reference to the pointer. But electrostatic instruments, containing, as they do, thin sheets of metal, subject to very small forces, must be provided with very delicate pivotting, and any bending or displacement of the "needles" is likely to give rise to serious errors. Internal sparking must be guarded against, and for low voltages contact difference between different metals, and even the degree of oxidation of the surfaces, must be allowed for. For voltages between 300 and 30,000, electrostatic voltmeters will hold their own. For lower pressures there is no apparent advantage, excepting, of course, those laboratory purposes for which electrometers are preferable. For very high voltages, such as are used in Teslaic experiments, electrostatic voltmeters become filled with brush discharges, but even if the whole of the working parts were immersed in oil, as has been done by Mr. Swinburne, they would not give any useful indication when interrupted currents and high-frequency discharges are used. For such researches an altogether new voltmeter has yet to be invented.

REVIEWS.

Dynamos, Alternators, and Transformers. By Gisbert Kapp, M.Inst.C.E., M.Inst.E.E. Illustrated. (London: Biggs and Co.)

In the preface the author states his object to be an exposition of the general principles of the construction of dynamo-electric apparatus, without the use of high mathematics and complicated methods of investigation, so that the average engineering student and the average practical engineer, *even if he have no previous knowledge of electrical science* (the italics are ours), can follow the subject. We sincerely hope both may be able to follow Mr. Kapp's admirable treatment of the matter, but we doubt it.

It is not easy for the author to "put himself in the place" of the average engineer who has simply mastered sufficient of the theory of electro-dynamics to couple-up and run a dynamo, and to make a few elementary calculations with reference to its output.

Mr. Kapp's new work is a fitting sequel to the various text-books. But, like all books that treat on subjects of large capacity and daily growth, it attempts too much, and consequently represents thoroughly but few of the many sides of the question, and necessarily assumes a closer acquaintance with elementary and fundamental facts than the average reader can possibly possess.

We find the index to be incomplete, and the sub-divisions of the chapters having no distinctive numbers, it is difficult to collect the references to any particular part of the subject. The utility of the book would be largely increased by a synopsis of the symbols and their meanings; as it is, we find it difficult to follow many of the equations.

In the first five chapters Mr. Kapp treats of the elementary conceptions of a magnetic field, and by a gradual transition leads up to the magnetic circuit of the dynamo. It is scarcely to be expected that an author can now-a-days find novel ways of dealing with this branch of the subject. Mr. Kapp lays some stress on the analogy of magnetism to a fluid, and the parallel certainly helps to explain the phenomena, and gives a physical interpretation to the equation of much value to the practical man. We also agree with the author that the term magnetic resistance is a most convenient one, and, used with the reservations he has made, it is of use in designing dynamo magnetic machinery. Much of the mathematics used in this portion of the book is, however, of a character better suited to text-books on magnetism, and, we fear, will have little attraction for the class of reader mentioned in the preface.

In Chapter VI. the magnetic properties of iron are discussed, and the terms hysteresis, permeability, and coercive force are elucidated both by mathematics and numerical examples. Chapter VII. brings us into touch with practice with the determination of the electromotive force, and the general question of armature-winding and pressure is enlarged upon in the next two chapters. This portion of

Digitized by Google

the book contains practical information with reference to bipolar and multipolar winding. The winding and potential-difference tables are new, and will certainly prove to be interesting to dynamo constructors. The various methods of avoiding the contiguity of wires at widely different pressures, though probably known to most machine constructors, are certainly not much practised, and yet they are worthy of special study. Field-magnets, determination of exciting power, and predetermination of characteristics, form the subject-matter for Chapter X. These questions have been treated in detail by various writers, and no doubt exception will be taken to much that the author says. The shape of a field-magnet is very much a matter of fancy on the part of the designer, and the accuracy of the predetermination of the "curve" depends very largely on his ability to make *scientific guesses* at certain coefficients and on a happy balancing of a number of factors, easy to settle on paper but difficult to control in the works. His expedient of showing at a glance the weight of copper in the windings by the depth of the black sections in the drawings is a useful device.

In Chapter XI. reference is made to the conditions necessary to secure a sparkless collection or commutation of current, and, as a necessary consequence, the back and cross turns of the armature are discussed, and a formula, for the "armature back ampere-turns" is given in this form, $X_b = \tau c \frac{a}{\pi}$; where τ = the number of conductors counted all round, c = the current in one conductor, and a = the angle of lead. And this is stated to be applicable to bipolar and multipolar machines; but the reader is left in doubt as to whether the Gramme and drum windings require the same compensating excitation. The equation, as it stands, appears to us to be approximately true for Grammes, but for drums we think it would be more nearly correct if the denominator were multiplied by two. And in both cases should not the equation be multiplied by the coefficient of magnetic leakage for full excitation?

A chapter is next devoted to the consideration of the influence of linear dimensions on the output, and the "critical" conditions of small and large dynamos. For the same efficiency the output of the larger machine will vary as the third power of the linear dimensions; for the same heating as the 5/2 power, and for the same sparking as the square. In criticising these statements, it should be noticed that they are true only when the two machines are identical in type and differ simply in size. The author also touches on the interesting question of losses in dynamos, and gives an experimental method of finding the power consumed by hysteresis, friction, and eddy currents at light and full load. Chapter XIV. is disappointing in some respects. It purports to give examples of dynamos in the market to-day, and we find the well-known and widely-built under-type two-pole drum dynamo illustrated by the machine of a firm scarcely known as builders of dynamos. We have nothing to say against the dynamo in question, but it cannot be said to be that of a representative constructor. The points of the over-type drum-armature class are shown by reference to one of Johnson and Phillips's "Kapp" dynamos. And the large, slow-speed, multipolar, Continental type is illustrated by one of the latest Oerlikon dynamos with a vertical shaft. And then follows a list of dynamos shown at the Crystal Palace last summer. The weak point about information derived from manufacturers at Exhibition times, when visions of gold medals are in the air, is that the coefficient of "errors in judgment" needs considerable correction.

In the next chapter the alternator is discussed in theory and practice. Electromotive force and other fundamental calculations are made without a very apparent use of sine functions, which will be a welcome addition to the practical literature of the subject. The effects of the "pitch ratio" of pole-pieces and armature coils is also fully discussed, for at least one case, and the constants for the more general designs are tabulated on page 374. Armature self-induction calculations are referred to in a simple manner, and it appears that the determination of the coefficient L (*i.e.*, the product of the square of the number of turns and the magnetic flux) is a very easy matter. Yet L is not a constant, but varies with the position of the coils; and although the limits of its values may not differ much in some machines, they appear to do so in others. We submit, then, our doubts as to the practical value of Mr. Kapp's equation for finding L in terms of the effective electromotive force of self-induction and the frequency and the effective current. The equation in practical units is given as follows:—

$$e = 2\pi n L i \quad . \quad . \quad . \quad . \quad . \quad . \quad (53).$$

It is obvious that L has a different value for different positions of the armature.

On page 387 Mr. Kapp discusses the "conditions for maximum power" in a given circuit, and states that these are satisfied when the pressure lost over the ohmic resistance is equal to the pressure of self-induction, and that they correspond to an angle of lag of 45deg. between the effective impressed pressure and the effective current. He concludes, if we understand him rightly, that an alternating motor must have a definite virtual resistance, and its self-induction must have a certain value in order to develop maximum power. And assuming the ohmic resistance of a given motor to be negligible compared with the self-induction, he states that the desired end is attained when the pressure required to overcome its self-induction equals the pressure required to overcome its counter electromotive force. It follows from this, he continues, that low frequencies are essential if the condition of maximum power is to be even approached. This investigation is of importance in connection with the alternate-motor question, and especially in reference to self-starting single-phase machines. In Chapter XVI. the effects of self-induction and capacity are illustrated both analytically and graphically, the equations being in practical units and free from trigonometrical functions, and the statics by Blakesley's well-known clock diagrams.

Parallel running is fully investigated, and the various problems likely to occur in practice. Then follow five interesting diagrams, all referring to parallel working, and showing the relations between armature and omnibus-bar pressures; and, finally, the necessity for regulation by adjustments of the driving power, and not by means of the excitation, is arrived at.

Mr. Kapp has investigated the effect of armature reactions in alternators, and arrives at the following equation for the value of the back ampere-turns:—

$$X_b = 0{\cdot}0156\, w\, i\, \phi \quad . \quad . \quad . \quad . \quad . \quad (59).$$

Where w is the number of active wires in one coil, i is the effective current, and ϕ is the angle of lag. The coefficient has been determined for a pitch ratio, in which poles, spaces, and coils are of equal width. The equation is evidently of the right order, for the reactions must vary with the current i, and with some function of the lag; but since these two terms vary inversely, the demagnetising effect may within wide limits be sensibly constant. Hence, although an alternator does not *necessarily* require compound coils, yet the ampere-turns necessary for the open-circuit pressure must be increased or diminished according as the armature current lags or leads. Mr. Kapp insists on "a reasonable amount of self-induction" as an essential in a good alternator for parallel running.

The conditions of stability of working, as generator or motor, are next elucidated in a series of intricate problems illustrated by diagrams. The effects of lead and lag in determining the range within which a given machine may be safely worked in either of those conditions is finally shown in Fig. 112. This part of the book is full of interesting matter, and several of the imperfectly understood phenomena occurring in practice, are, if not thoroughly explained, at any rate, considerably simplified. Amongst others the apparently singular fact that two alternators of widely differing open circuit pressures may be coupled in parallel, and will then run at a terminal pressure approximately equal to the arithmetical mean between the two open-circuit pressures. The general conclusions at the end of this section summarise the known facts of alternate-current working. These are, of course, recognised by most of the more prominent electrical engineers; but some of Mr. Kapp's deductions will be challenged, and some of his theories will be attacked. This is to be expected.

Digitized by Google

The next chapter is devoted to transformers. It necessarily suffers somewhat by comparison with Dr. Fleming's recent work on the same subject, but, nevertheless, forms a short pithy statement of theory, and most of the practical conditions of working are discussed and their graphical treatment suggested by clock diagrams. The effects of self-induction and capacity on the voltage drop and the importance of restricting the magnetising currents within small limits are abundantly shown. The final chapter is a *résumé* of the better-known alternators, and forms a fitting conclusion to the book.

"Dynamos, Alternators, and Transformers" is a book that will be invaluable to the advanced student and the dynamo-designer, but we fear it will prove too difficult reading for the average engineer. There are a few misprints, chiefly in equations; but they are obviously printers' errors, and the corrections are apparent. A. T. S.

AYRTON AND MATHER'S ELECTROSTATIC VOLTMETER.

An electrostatic voltmeter designed by Prof. Ayrton and Mr. T. Mather, and made by Mr. R. W. Paul, is shown in Fig. 1.

FIG. 1.

The working parts of the instrument are shown diagrammatically in Fig. 2. The parts A, B, C, are the fixed inductors, corresponding to the quadrants of an electrometer. These inductors are curved brass plates, the edges and corners being carefully rounded to prevent sparking. They are connected

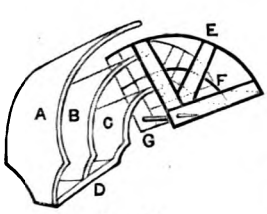

FIG. 2.

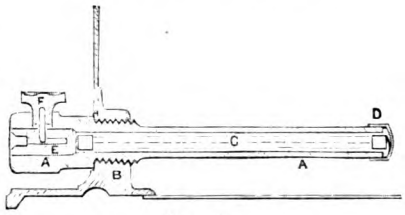

FIG. 3.

together by the plate D. The "needle," E, F, consists of two thin curved aluminium plates, concentric with the staff G, which carries them. These plates are drawn into the space between the inductors by the electrostatic attraction between them, and are counterpoised by the hand and controlled by a weight attached to an arm on the staff so as to bring the hand to zero. Their moment of inertia is so small that the needle takes its position of equilibrium rapidly. The dial is supported on ebonite pillars, and surrounded by a bezel ring of ebonite, which prevents contact with the outer case; the latter is, therefore, entirely insulated from the circuit. Each terminal, of which a section is shown in Fig. 3, is cased in ebonite, so that a person connecting up cannot receive a shock from it. The hollow ebonite portion, A, A, contains a brass block E embedded near its outer end, and covered by an ebonite nipple; the block is tapped for the set screw F, which holds the wire in place. The part of A which projects into the case, into which it screws at B, contains a fuse of platinum silver 0·001in. diameter, enclosed in a glass tube with metal caps, to which it is connected. They make contact with the block E at one end, and the spring cap D at the other. The cap D makes contact in turn with the connecting spring mentioned above. The fuses are therefore very easily replaced. A spark-gap is arranged inside the voltmeter, and is adjusted so that, in case of abnormal rise of pressure, sparking will occur at the gap and produce no damage. The scale has a movable index and has a radius of 6in. and a length of 10in. The instruments at present made are suitable for circuits at 500, 1,000, 2,000, and 2,400 volts.

THE FORTHCOMING INTERNATIONAL ELECTRICAL CONGRESS AT CHICAGO.

The following is a *résumé* of the preliminary programme of the International Electrical Congress to be held in Chicago in August:—

On Monday, August 21st, at 3 p.m., the Opening Session of the General Congress will be held, and permanent officers, &c., will be nominated. At the close of this meeting the Chamber of Delegates will assemble for preliminary organisation. The Chamber of Delegates will consist of the official delegates from the various Governments.

The General Congress will be divided into three sections, as follows:—(A) Section of Pure Theory. (B) Section of Theory and Practice. (C) Section of Pure Practice. These sections will meet for organisation and work at 10 a.m. on Tuesday, August 22nd. Temporary presiding officers will be as follows:—Section A, Prof. H. A. Rowland; Section B, Prof. Charles R. Cross; Section C, Prof. A. Graham Bell. These sections will meet at 10 a.m. on Tuesday, Wednesday, Thursday, and Friday, continuiug in session at will, except on Friday, when they will finally adjourn as Sections not later than 1 p.m. Each Section will have authority to divide into sub-sections if it is thought to be desirable.

At the meetings of these sections, Papers will be read, followed by discussions.* The Papers should be sent to the Chairman of the Programme Committee, Prof. T. C. Mendenhall, Washington, D.C., not later than August 1, 1893. Such as are accepted by that Committee will be put upon the programme of the Congress, to be presented in full or by abstract according to the time available.

The following topics will be considered by the Chamber of Delegates:—Adoption of definitions and values of fundamental units of resistance, current and electromotive force.—Adoption of definitions and values of magnetic units.—Adoption of definition and value of the unit of self-induction.—Definitions and values of light, energy, and other units.—The standardisation of electric lights.—The consideration of an international system of notation and conventional symbols, and of a more uniform and accurate use of terms and phrases in electrical literature.—A commercial standard of copper resistance.

The hours of meeting for the Chamber of Delegates will be determined, after the first session, by the Chamber itself; and it will also decide upon the admission of persons not delegates to its sittings. It will finally adjourn, not later than 1 p.m. on Friday, August 25th, and at the last meeting of the General Congress, the officers of the Chamber will report to it a summary of its proceedings and the conclusions reached.

The General Congress will assemble to hear reports and for final adjournment at 3 p.m., Friday, August 25th.

* The subjects, upon which Papers are solicited, will be found on page 215 of our issue of December 23, 1892.—ED. *E.*

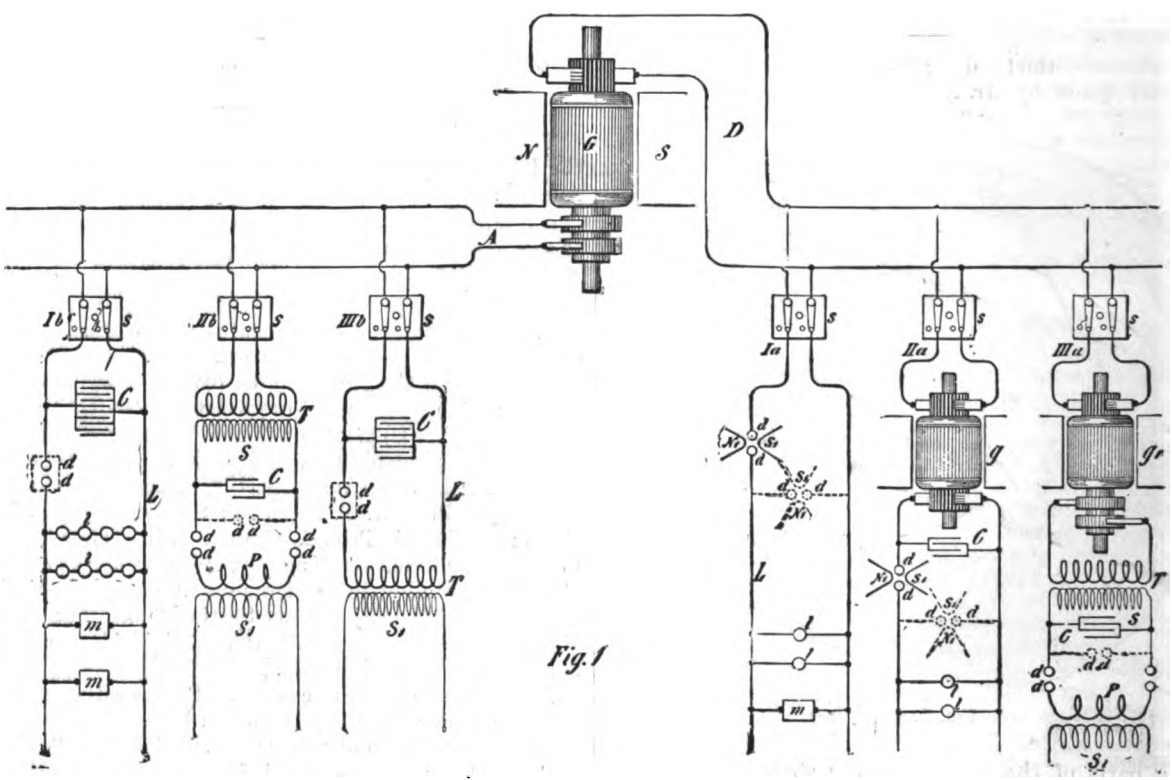
ON LIGHT AND OTHER HIGH-FREQUENCY PHENOMENA.*

BY NIKOLA TESLA.

A number of ways, as practised in the laboratory, of obtaining high-frequency currents either from continuous or low-frequency alternating currents are diagrammatically indicated in Fig. 1, which will be later described in detail. The general plan is to charge condensers, from a direct or alternate-current source, preferably of high-tension, and to discharge them disruptively while observing well-known conditions necessary to maintain the oscillations of the current. In view of the general interest taken in high-frequency currents and effects producible by them, it seems to me advisable to dwell at some length upon this method of conversion. In order to give you a clear idea of the action, I will suppose that a continuous-current generator is employed, which is often very convenient. It is desirable that the generator should possess such high tension as to be able to break through a small air-space. If this is not the case, then auxiliary means have to be resorted to, some of which will be indicated subsequently. When the condensers are charged to a certain potential, the air or insulating space gives way and a disruptive discharge occurs. There is then a sudden rush of current, and generally a large portion of the accumulated electrical energy spends itself. The condensers are thereupon



Plan of Connections Used in the Conversion by Means of the Disruptive Arc Discharge.

quickly charged, and the same process is repeated in more or less rapid succession. To produce such sudden rushes of current it is necessary to observe certain conditions. If the rate at which the condensers are discharged is the same as that at which they are charged, then, clearly, in the assumed case the condensers do not come into play. If the rate of discharge be smaller than the rate of charging, then, again, the condensers cannot play an important part. But if, on the contrary, the rate of discharging is greater than that of charging, then a succession of rushes of current is obtained.

A form of discharger with a magnet which has been found convenient, and adopted after some trials, in the conversion of direct currents particularly, is illustrated in Fig. 2. N S are the pole-pieces of a very strong magnet which is excited by a coil C. The pole-pieces are slotted for adjustment and can be fastened in any position by screws s_1 s_1. The discharge rods d d_1 thinned down on the ends in order to allow a closer approach of the magnetic pole-pieces, pass through the columns of brass b b_1, and are fastened in position by screws s_2 s_2. Springs r r_1 and collars c c_1 are slipped on the rods, the latter serving to set the points of the rods at a certain suitable distance by means of screws s_3 s_3, and the former to draw the points apart. When it is desired to start the arc, one of the hard rubber handles h h_1 is tapped quickly with the hand, whereby the points of the rods are brought in contact, but are instantly separated by the springs r r_1. Such an arrangement has been found to be often necessary, namely, in cases when the E.M.F. was not large enough to cause the discharge to break through the gap, and also when it was desirable to avoid short circuiting of the generator by the metallic contact of the rods. The rapidity of the interruptions of the current with a magnet depends on the intensity of the magnetic field and on the potential difference at the ends of the arc.

When the current through the gap is comparatively large, it is of advantage to slip on the points of the discharge rods pieces of very hard carbon and let the arc play between the carbon pieces. This preserves the rods and besides has the advantage of keeping the air-space hotter, as the heat is not conducted away as quickly through the carbons, and the result is that a smaller E.M.F. in the arc gap is required to maintain a succession of discharges.

In another form of discharger the discharge rods pass through perforations in a wooden box, which is thickly coated with mica on the inside. The spark-gap is warmed by a small lamp contained in the box. The air being warmed to a certain temperature has its insulating power impaired, it becomes dielectrically weak, as it were, and the consequence is that the arc can be established at much greater distance. The air should, of course, be sufficiently insulating to allow the discharge to pass through the gap *disruptively*. The arc formed under such conditions, when long, may be made extremely sensitive, and the weak draught through the lamp chimney is quite sufficient to produce rapid interruptions. The adjustment is made by regulating the temperature and velocity of the draught.

It should be remarked here that when such, or interrupting devices of any kind, are used and the currents are passed through the primary of a disruptive discharge coil, it is not, as a rule, of advantage to produce a number of interruptions of the current per second greater than the natural frequency of vibration of the dynamo supply circuit, which is ordinarily small.

The ideal medium for a discharge gap should only *crack*, and the ideal electrode should be of some material which cannot be disintegrated. With small currents through the gap it is best to employ aluminum, but not when the currents are large. The disruptive break in the air, or more or less in any ordinary medium, is not of the nature of a crack, but it is rather comparable to the piercing of innumerable bullets through a mass offering great frictional resistance to the motion of the bullets, this involving considerable loss of energy. As a medium for the discharge space a solid, or even a liquid, would be preferable therefore. It is somewhat difficult to conceive of a solid body which would possess the property of closing instantly after it has been cracked. But a liquid, especially under great pressure, behaves practically like a

* Abstract of a lecture delivered before the Franklin Institute, at Philadelphia, February 24, 1893, and before the National Electric Light Association, at St. Louis, Mo., March 1, 1893. We are indebted to the *Electrical World*, of New York, for the blocks illustrating this lecture.

Digitized by Google

solid, while it possesses the property of closing the crack. Hence it was thought that a liquid insulator might be more suitable as a dielectric than air. Following out this idea, a number of different forms of dischargers in which a variety of such insulators sometimes under great pressure were employed, have been experimented upon. It is thought sufficient to dwell, in a few words, upon one of the forms experimented upon. One of these dischargers is illustrated in Figs. 4*a* and 4*b*.

A hollow metal pulley, P (Fig. 4*a*), was fastened upon an arbor, *a*, which by suitable means was rotated at a considerable speed. In the inside of the pulley, but disconnected from the same, was supported a thin disc h_1 (which is shown thick for the sake of clearness) of hard rubber, in which there were embedded two metal segments, *s s*, with metallic extensions, *e e*, into which were screwed conducting terminals, *t t*, covered with thick tubes of hard rubber, *t t*. The rubber disc, *h*, with its metallic segments, S S, was

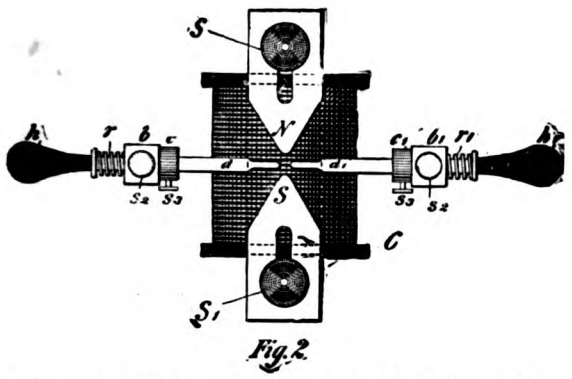


Fig. 2.

Form of Discharger with Magnet Used in the Direct-Current Conversion.

finished in a lathe, and its entire surface highly polished so as to offer the smallest possible frictional resistance to the motion through a fluid. In the hollow of the pulley an insulating liquid, such as a thin oil, was poured, so as to reach very nearly to the opening left in the flange *f*, which was screwed tightly on the front side of the pulley. The terminals, *t t*, were connected to the opposite coatings of a battery of condensers, so that the discharge occurred through the liquid. When the pulley was rotated the liquid was forced against the rim of the pulley, and considerable fluid pressure resulted. In this simple way the discharge gap was filled with a medium which behaved practically like a solid, which possessed the quality of closing instantly upon the occurrence of the break, and which, moreover, was circulating through the gap at a rapid rate. Very powerful effects were produced by dischargers of this kind with liquid interrupters, of which a number of different forms were made. It was found that, as expected, a longer spark for a given length of wire was obtainable in this way than by using air as an interrupting device.

Form of Discharger with Liquid Interrupter.

In the diagrammatical sketch (Fig. 1) which has been already, referred to, the cases which are most likely to be met with in practice are illustrated. One has at his disposal either direct or alternating currents from a supply station. It is convenient for an experimenter in an isolated laboratory to employ a machine G such as illustrated, capable of giving both kinds of currents. In such case it is also preferable to use a machine with multiple circuits, as in many experiments it is useful and convenient to have at one's disposal currents of different phases. In the sketch, D represents the direct and A the alternating circuit. In each of these, three branch circuits are shown, all of which are provided with double lines switches, *s s s s s s*. Consider first the direct current conversion; I *a* represents the simplest case. If the E.M.F. of the generator is sufficient to break through a small air-space, at least, when the latter is warmed or otherwise rendered poorly insulating, there is no difficulty in maintaining a vibration with fair economy by judicious adjustment of the capacity, self-induction and resistance of the circuit L containing the devices *l l m*. The magnet N, S, can be in this case advantageously combined with the air-space. The discharger *d d* with the magnet may be placed either way, as indicated by the full or by the dotted lines. The circuit I *a* with the connections and devices is supposed to possess dimensions such as are suitable for the maintenance of a vibration. But usually the E.M.F. on the circuit or branch (Fig. 1), I *a* will be something like 100 volts or so, and in this case it is not sufficient to break through the gap. Many different means may be used to remedy this by raising the E.M.F. across the gap. The simplest is probably to insert a large self-induction coil in series with the circuit L. When the arc is established, as by the discharger (illustrated in Fig. 2), the magnet blows the arc out the instant it is formed. Now the extra current of the break, being of high E.M.F., breaks through the gap, and a path of low resistance for the dynamo current being again provided, there is a sudden rush of the current from the dynamo upon the weakening or subsidence of the extra current. This process is repeated in rapid succession, and in this manner I have maintained oscillation with as low as 50 volts, or even less, across the gap. But conversion on this plan is not to be recommended, on account of the too heavy currents through the gap and consequent heating of the electrodes; besides, the frequencies obtained in this way are low, owing to the high self-induction necessarily associated with the circuit. It is very desirable to have the E.M.F. as high as possible, firstly, in order to increase the economy of the conversion, and, secondly, to obtain high frequencies. The difference of potential in this electric oscillation is, of course, the equivalent of the stretching force in the mechanical vibration of the spring. To obtain very rapid vibration in a circuit of some inertia a great stretching force or difference of potential is necessary. Incidentally, when the E.M.F. is very great, the condenser, which is usually employed in connection with the circuit, need have but a small capacity, and many other advantages are gained. With a view of raising the E.M.F. to a many times greater value than obtainable from ordinary distribution circuits, a rotating transformer *g* is used, as indicated in Fig. II*a*., or else a separate high-potential machine is driven by means of a motor operated from the generator G. The latter plan is in fact preferable, as changes are easier made. The connections from the high-tension winding are quite similar to those in branch 1*a* with the exception that a condenser C, which should be adjustable, is connected to the high-tension circuit. Usually, also, an adjustable self-induction coil in series with the circuit has been employed in these experiments. When the tension of the currents is very high the magnet ordinarily used in connection with the discharger is of comparatively small value, as it is quite easy to adjust the dimensions of the circuit so that oscillation is maintained. The employment of a steady E.M.F. in the high-frequency conversion affords some advantages over the employment of alternating E.M.F., as the adjustments are much simpler and the action can be easier controlled. But, unfortunately, one is limited by the obtainable potential difference. The windings also break down easily in consequence of the sparks which form between the sections of the armature or commutator when a vigorous oscillation takes place. Besides, these transformers are expensive to build. It has been found by experience that it is best to follow the plan illustrated in Fig. 1, III*a*. In this arrangement a rotating transformer *g* is employed to convert the low-tension direct currents into low-frequency alternating currents, preferably also of small tension. The tension of the currents is then raised in a stationary transformer T. The secondary S of this transformer is connected to an adjustable condenser C which discharges through the gap or discharger *d d*, placed in either of the ways indicated, through the primary P of a disruptive discharge coil, the high-frequency currents being obtained from the secondary S of this coil, as described on previous occasions. This will undoubtedly be found the cheapest and most convenient way of converting direct currents.

The three branches of the circuit A represent the usual cases met in practice when alternating currents are converted. In Fig. 1, I *b* a condenser C, generally of large capacity, is connected to the circuit L containing the devices *l l*, *m m*. The devices *m m* are supposed to be of high self-induction so as to bring the frequency of the circuit more or less to that of the dynamo. In this instance the discharger *d d* should best have a number of makes and breaks per second equal to twice the frequency of the dynamo. If not so, then it should have at least a number equal to a multiple or even fraction of the dynamo frequency. It should be observed, referring to (Fig. 1), I *b*, that the conversion to a high potential is also effected when the discharger *d d*, which is shown in the sketch, is omitted. But the effects which are produced by currents which rise instantly to high values, as in a disruptive discharge, are entirely different from those produced by dynamo currents which rise and fall harmonically. So, for instance, there might be in a given case a number of makes and breaks at *d d* equal to just twice the frequency of the dynamo, or, in other words, there may be the same number of fundamental oscillations as would be produced without the discharge gap, and there might even not be any quicker superimposed vibration; yet the differences of potential at the various points of the circuit, the impedence and other phenomena,

Digitized by Google

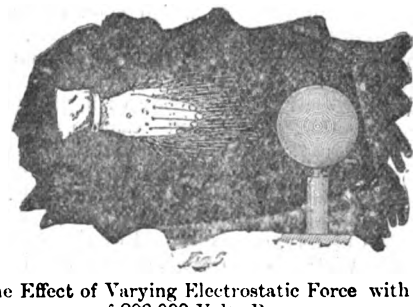
dependent upon the rate of change, will bear no similarity in the two cases. Thus, when working with currents discharging disruptively, the element chiefly to be considered is not the frequency, as a student might be apt to believe, but the rate of change per unit of time. With low frequencies in a certain measure the same effects may be obtained as with high frequencies, provided the rate of change is sufficiently great. So, if a low-frequency current is raised to a potential of, say, 75,000 volts and the high-tension current passed through a series of high-resistance lamp filaments, the importance of the rarefied gas surrounding the filament is clearly noted, as will be seen later; or, if a low-frequency current of several thousand amperes is passed through a metal bar, striking phenomena of impedence are observed, just as with currents of high frequencies. But it is, of course, evident that with low-frequency currents it is impossible to obtain such rates of change per unit of time as with high frequencies, hence the effects produced by the latter are much more prominent. It was deemed advisable to make the preceding remarks, inasmuch as many more recently described effects have been unwittingly identified with high frequencies. Frequency alone in reality does not mean anything, except when an undisturbed harmonic oscillation is considered.

In the branch Fig. 1 III.*b* a similar disposition to that in 1*b* is illustrated, with the difference that the currents discharging through the gap *d d* are used to induce currents in the secondary S of a transformer, T. In such case the secondary should be provided with an adjustable condenser for the purpose of tuning it to the primary.

Fig. 1 II.*b* illustrates a plan of alternate-current high-frequency conversion which is most frequently used, and which is found to be most convenient. This plan has been dwelt upon in detail on previous occasions, and need not be described here.

I will now proceed with the experiments.

On one of the terminals of the coil I have placed a large sphere of sheet brass, which is connected to a larger insulated brass plate, in order to enable me to perform the experiments under conditions, which, as you will see, are more suitable for this experiment. I now set the coil to work, and approach the free terminal with a metallic object held in my hand, this simply to avoid burns. As

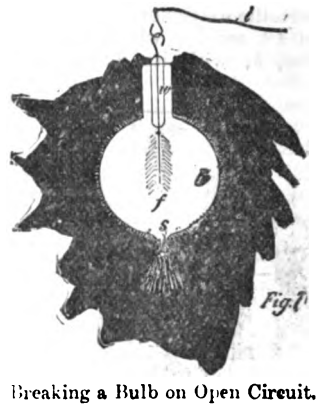


Illustrating the Effect of Varying Electrostatic Force with a Transformer of 200,000 Volts Pressure.

I approach the metallic object to a distance of 8in. or 10in., a torrent of furious sparks breaks forth from the end of the secondary wire, which passes through the rubber column. My arm is now traversed by a powerful electric current, vibrating at about the rate of one million times a second. I can make these streams of light visible to all, by touching with the metallic object one of the terminals as before, and approaching my free hand to the brass sphere, which is connected to the second terminal of the coil. As the hand is approached, the air between it and the sphere, or in the immediate neighbourhood, is more violently agitated, and you see streams of light now break forth from my finger tips and from the whole hand (Fig. 5). Were I to approach the hand closer, powerful sparks would jump from the brass sphere to my hand, which might be injurious. The streamers offer no particular inconvenience, except that in the ends of the finger tips a burning sensation is felt. They should not be confounded with those produced by an influence machine, because in many respects they behave differently. I have attached the brass sphere and plate to one of the terminals, in order to prevent the formation of visible streamers on that terminal, also in order to prevent sparks from jumping at a considerable distance. Attachment is favourable for the working of the coil.

The streams of light which you have observed issuing from my hand are due to a potential of about 200,000 volts, alternating in rather irregular intervals, something like a million times a second. A vibration of the same amplitude, but four times as fast, to maintain which over 3,000,000 volts would be required, would be more than sufficient to envelop my body in a complete sheet of flame. But this flame would not burn me up; quite contrarily, the probability is that I would not be injured in the least. Yet a hundredth part of that energy, otherwise directed, would be amply sufficient to kill a person.

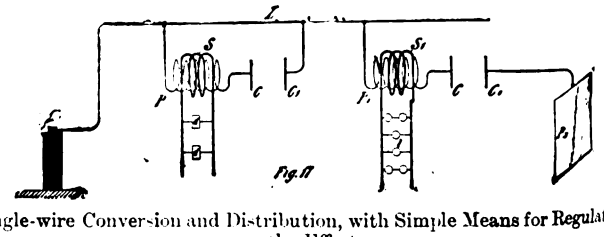
The amount of energy which may thus be passed into the body of a person depends on the frequency and potential of the currents, and by making both of these very great, a vast amount of energy may be passed into the body without causing any discomfort, except perhaps, in the arm, which is traversed by a true conduction current. The reason why no pain in the body is felt, and no injurious effect noted, is that everywhere, if a current be imagined to flow through the body, the direction of its flow would be at right angles to the surface; hence the body of the experimenter offers an enormous section to the current, and the density is very small, with the exception of the arm, perhaps, where the density may be considerable. But if only a small fraction of that energy would be applied in such a way that a current would traverse the body in the same manner as a low-frequency current, a shock would be received which might be fatal.



Breaking a Bulb on Open Circuit.

I now return to the experiment to which I have already alluded, and with which I desire to illustrate a striking effect produced by a rapidly varying electrostatic force. I attach to the end of the wire *l* (Fig. 7), which is in connection with one of the terminals of the secondary of the induction coil, an exhausted bulb *b*. The bulb contains a thin carbon filament, *f*, which is fastened to a platinum wire, *w*, sealed in the glass, and leading outside of the bulb, where it connects to the wire *l*. The bulb may be exhausted to any degree attainable with ordinary apparatus. Just a moment before you have witnessed the breaking down of the air between the charged brass plates. You know that a plate of glass, or any other insulating material, would break down in like manner. Had I, therefore, a metallic coating attached to the outside of the bulb, or placed near the same, and were this coating connected to the other terminal of the coil, you would be prepared to see the glass give way if the strain were sufficiently increased. Even were the coating not connected to the other terminal, but to an insulated plate, still, if you have followed recent developments, you would naturally expect a rupture of the glass.

But it will certainly surprise you to note that under the action of the varying electrostatic force, the glass gives way when all other bodies are removed from the bulb. In fact, all the surrounding bodies we perceive might be removed to an infinite distance without affecting the result in the slightest. When the coil is set to work, the glass is invariably broken through at the seal, or other



Single-wire Conversion and Distribution, with Simple Means for Regulating the Effects.

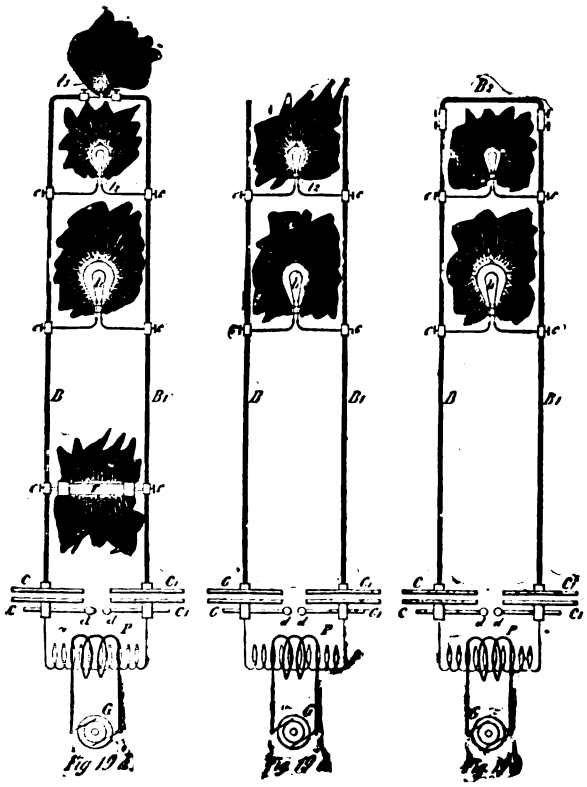
narrow channel, and the vacuum is quickly impaired. Such a damaging break would not occur with a steady force, even if the same were many times greater. The break is due to the agitation of the molecules of the gas within the bulb and outside of the same. This agitation, which is generally most violent in the narrow-pointed channel near the seal, causes a heating and rupture of the glass. This rupture would, however, not occur, not even with a varying force, if the medium filling the inside of the bulb and that surrounding it were perfectly homogeneous. The break occurs much quicker if the top of the bulb is drawn out into a fine fibre. In bulbs used with these coils such narrow-pointed channels must therefore be avoided.

When the frequencies are very high it has been found in laboratory practice quite easy to regulate the effects in the manner shown in diagram Fig. 17. Here two primaries P and P are shown, each connected with one of its ends to the line L, and with the other end to the condenser plates C and C^1, respectively. Near these are placed other condenser plates C_1 and C^1_1, the former being

Digitized by Google

connected to the line L and the latter to an insulated larger plate, P_2. On the primaries are wound secondaries S and S_1 of coarse wire. By varying the distances of the condenser plates C and C^1, the currents through the secondaries S and S^1 are varied in intensity. The curious feature is the great sensitiveness, the slightest change in the distance of the plates producing considerable variations in the intensity or strength of the currents. The sensitiveness may be rendered extreme by making the frequency such, that the primary itself without any plate attached to its free end satisfies, in conjunction with the closed secondary, the condition of resonance. In such condition an extremely small change in the capacity of the free terminal produces great variations. For instance, I have been able to adjust the conditions so that the mere approach of a person to the coil produces a considerable change in the brightness of the lamps attached to the secondary. Such observations and experiments possess, of course, at present chiefly scientific interest, but they may soon become of practical importance.

Among the various current phenomena observed perhaps the most interesting are those of impedence presented by conductors to currents varying at a rapid rate. In my first Paper before the American Institute of Electrical Engineers, I have described a few striking observations of this kind. Thus I showed that when such currents or sudden discharges are passed through a thick metal bar there may be points at the bar only a few inches apart, which have a sufficient potential difference between them to maintain at bright incandescence an ordinary filament lamp. I have also described the curious behaviour of rarefied gas surrounding a

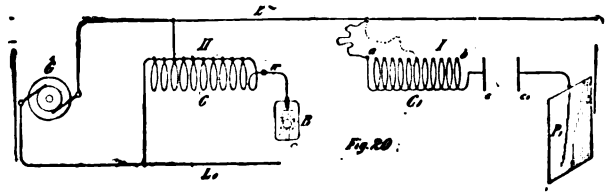


Impedance Phenomena.

conductor to such sudden rushes of current. These phenomena have been since more carefully studied and one or two novel experiments of this kind are deemed of sufficient interest to be described here.

With reference to Fig. 19*a*, B and B_1 are very stout copper bars connected at their lower ends to plates C and C_1 respectively of a condenser, the opposite plates of the latter being connected to the terminals of the secondary S of a high-tension transformer, the primary P of which is supplied with alternating currents from an ordinary low-frequency dynamo G or distribution circuit. The condenser discharges through an adjustable gap *d d* as usual. By establishing a rapid vibration, it was found quite easy to perform the following curious experiment :—The bars B and B_1 were joined at the top by a low-voltage lamp l_3 ; a little lower, was placed, by means of clamps *c c*, a 50-volt lamp l_2, and still lower another 100-volt lamp l_1 ; and finally, at a certain distance below the latter lamp, an exhausted tube T. By carefully determining the positions of these devices, it was found practicable to maintain them all at their proper illuminating power. Yet they were all connected in multiple arc to the two stout copper bars, and required widely different pressures. This experiment requires, of course, some time for adjustment, but is quite easily performed.

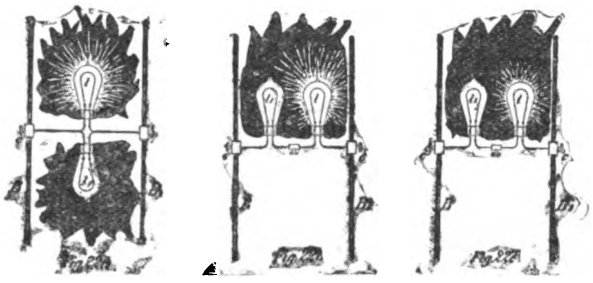
In Figs. 19*b* and 19*c*, two other experiments are illustrated, which, unlike the previous experiment, do not require very careful adjustments. In Fig. 22*b*, two lamps, l_1 and l_2, the former a 100-volt and the latter a 50-volt, are placed in certain positions as indicated, the 100-volt lamp being below the 50-volt lamp. When the arc is playing at *d d*, and the sudden discharges passed through the bars B B, the 50-volt lamp will, as a rule, burn brightly, or at least this result is easily secured, while the 100-volt lamp will burn very low or remain quite dark (Fig. 19*b*). Now the bars B B may be joined at the top by a thick cross-bar B_2, and it is quite easy to maintain the 100-volt lamp at full candle-power while the 50 volt lamp remains dark (Fig. 19*c*). These results, as I have pointed out previously, should not be considered to be due exactly to frequency, but rather to the time rate of change, which may be great even with low frequencies.



Plan Followed in Observing the Effects of Resonance.

In Fig. 20, I., is shown a plan which has been followed in the study of the resonance effects by means of a high-frequency alternator. C is a coil of many turns, which is divided in small separate sections for the purposes of adjustment. The final adjustment was made sometimes with a few thin iron wires (though this is not always advisable) or with a closed secondary. The coil C is connected with one of its ends to the line L from the alternator G and with the other end to one of the plates *c* of a condenser *c* c_1, the plate (c_1) of the latter being connected to a much larger plate P_1. In this manner both capacity and self-induction were adjusted to suit the dynamo frequency.

As regards the rise of potential through resonant action, of course, theoretically, it may amount to anything since it depends on self-induction and resistance and since these may have any value. But in practice one is limited in the selection of these values, and besides these there are other limiting causes. One may start with, say, 1,000 volts, and raise the E.M.F. to 50 times that value, but one cannot start with 100,000 and raise it to ten times that value because of the losses in the media, which are great, especially if the frequency is high. It should be possible to start with, for instance, two volts from a high or low frequency circuit of a dynamo and raise the E.M.F. to many hundred times that value. Thus coils of the proper dimensions might be connected each with only one of its ends to the mains from a machine of low E.M.F., and though



Showing the Effect of the Presence of a Gaseous Medium.

the circuit of the machine would not be closed in the ordinary acceptance of the term, yet the machine might be burned out if a proper resonance effect would be obtained. I have not been able to produce, nor have I observed with currents from the dynamo machine, such great rises of potential. It is possible, if not probable, that with currents obtained from apparatus containing iron the disturbing influence of the latter is the cause that these theoretical possibilities cannot be realised. But if such is the case I attribute it solely to the hysteresis and Foucault current losses in the core. Generally it was necessary to transform upward, when the E.M.F. was very low, and usually an ordinary form of induction coil was employed, but sometimes the arrangement illustrated in Fig. 20, II., has been found to be convenient. In this case a coil C is made in a great many sections, a few of these being used as the primary. In this manner both primary and secondary are adjustable. One end of the coil is connected to the line L_1 from the alternator, and the other line L is connected to the intermediate point of the coil. Such a coil with adjustable primary and secondary will be found also convenient in experiments with the disruptive discharge. When true resonance is obtained the top of the wave must of course be on the free end of the coil as, for instance, at the terminal of the phosphorescence bulb B. This is easily recognised by observing the potential of a point on the wire *w* nearer to the coil.

Digitized by Google

In connection with resonance effects and the problem of transmission of energy over a single conductor, which was previously considered, I would say a few words on a subject which constantly fills my thoughts and which concerns the welfare of all. I mean the transmission of intelligible signals, or perhaps even power, to any distance without the use of wires. We now know that electric vibration may be transmitted through a single conductor. Why, then, not try to avail ourselves of the earth for this purpose?

A point of great importance would be first to know what is the capacity of the earth; and what charge does it contain if electrified. Though we have no positive evidence of a charged body existing in space without other oppositely electrified bodies being near, there is a fair probability that the earth is such a body, for by whatever process it was separated from other bodies—and this is the accepted view of its origin—it must have retained a charge, as occurs in all processes of mechanical separation. If it be a charged body insulated in space its capacity should be extremely small, less than one-thousandth of a farad. But the upper strata of the air are conducting, and so, perhaps, is the medium in free space beyond the atmosphere, and these may contain an opposite charge. Then the capacity might be incomparably greater. In any case it is of the greatest importance to get an idea of what quantity of electricity the earth contains. It is difficult to say whether we shall ever acquire this necessary knowledge, but there is hope that we may, and that is, by means of electrical resonance. If ever we can ascertain at what period the earth's charge, when disturbed, oscillates with respect to an oppositely electrified system or known circuit, we shall know a fact possibly of the greatest importance to the welfare of the human race. I propose to seek for the period by means of an electrical oscillator, or a source of alternating electric currents. One of the terminals of the source would be connected to earth as, for instance, to the city water mains, the other to an insulated body of large surface. It is possible that the outer conducting air strata, or free space, contains an opposite charge, and that, together with the earth, they form a condenser of very large capacity. It is certainly practicable to impress an electric vibration, at least of a certain low period, upon the earth, by means of proper machinery. At what distance such a vibration might be made perceptible can only be conjectured. I think that beyond doubt it is possible to operate electrical devices in a city through the ground or pipe system by resonance from an electrical oscillator located at a central point. But the practical solution of this problem would be of incomparably smaller benefit to man than the realisation of the scheme of transmitting intelligence or, perhaps, power to any distance through the earth or environing medium.

On the Light Phenomena produced by High-frequency Currents of High Potential and General Remarks relating to the Subject.

Returning now to the light effects which it has been the chief object to investigate, it is thought proper to divide these effects into four classes:—(1) Incandescence of a solid; (2) Phosphorescence; (3) Incandescence or phosphorescence of a rarefied gas; and (4) Luminosity produced in a gas at ordinary pressure. The first question is, How are these luminous effects produced?

In Figs. 22*a*, 22*b*, and 22*c* the heavy copper bars B B_1 are connected to the opposite coatings of a battery of condensers, or generally in such way that the high frequency or sudden discharges are made to traverse them. I connect first an ordinary 50-volt incandescent lamp to the bars by means of the clamps *c c*. The discharges being passed through the lamp, the filament is rendered incandescent, though the current through it is very small, and would not be nearly sufficient to produce a visible effect under the conditions of ordinary use of the lamp. Instead of this I now attach to the bars another lamp exactly like the first, but with the seal broken off, the bulb being therefore filled with air at ordinary pressure. When the discharges are directed through the filament, as before, it does not become incandescent. But the result might still be attributed to one of the many possible reactions. I therefore connect both the lamps in multiple arc as illustrated in Fig. 22*a*. Passing the discharges through both the lamps, again the filament in the exhausted lamp *l* glows very brightly, while that in the non-exhausted lamp l_1 remains dark, as previously. But it should not be thought that the latter lamp is taking only a small fraction of the energy supplied to both the lamps; on the contrary, it may consume a considerable portion of the energy and it may become even hotter than the one which burns brightly. In this experiment the potential difference at the terminals of the lamps varies in sign theoretically three to four million times a second. The ends of the filaments are correspondingly electrified, and the gas in the bulbs is violently agitated and a large portion of the supplied energy is thus converted into heat. In the non-exhausted bulb there being a few million times more gas molecules than in the exhausted one, the bombardment, which is most violent at the ends of the filament, in the neck of the bulb, consumes a large portion of the energy without producing any visible effect. The reason is that, there being many molecules, the bombardment is quantitatively considerable, but the individual impacts are not very violent, as the speeds of the molecules are comparatively small owing to the small free path. In the exhausted bulb, on the contrary, the speeds are very great and the individual impacts are violent, and therefore better adapted to produce a visible effect. Besides, the convection of heat is greater in the former bulb. In both the bulbs the current traversing the filaments is very small, incomparably smaller than that which they require on an ordinary low-frequency circuit. The potential difference, however, at the ends of the filaments is very great and might be possibly 20,000 volts or more, if the filaments were straight and their ends far apart. In the ordinary lamp a spark generally occurs between the ends of the filament or between the platinum wires outside before such a difference of potential can be reached.

It might be objected in the experiment before shown that the lamps being in multiple arc, the exhausted lamp might take a much larger current, and that the effect observed might not be exactly attributable to the action of the gas in the bulbs. Such objections will lose much weight if I connect the lamps in series, with the same result. When this is done, and the discharges are directed through the filaments, it is again noted that the filament in the non-exhausted bulb, l_1, remains dark, while that in the exhausted one, *l*, glows even more intensely than under its normal conditions of working (Fig. 22*b*). According to general ideas the current through the filaments should now be the same, were it not modified by the presence of the gas around the filaments.

At this juncture I may point out another interesting feature, which illustrates the effect of the rate of change of potential of the currents. I will leave the two lamps connected in series to the bars B B_1, as in the previous experiment (Fig. 22*b*), but will presently reduce considerably the frequency of the currents, which was excessive in the experiment just before shown. This I may do by inserting a self-induction coil in the path of the discharges, or by augmenting the capacity of the condensers. When I now pass these low-frequency discharges through the lamps, the exhausted lamp, *l*, again is as bright as before, but it is noted also that the non-exhausted lamps, l_1, glows, though not quite as intensely as the other. Reducing the current through the lamps, I may bring the filament in the latter lamp to redness, and, though the filament in the exhausted lamp, *l*, is bright (Fig. 22*c*), the degree of its incandescence is much smaller than in Fig 22*b*, when the currents were of a much higher frequency.

(To be continued.)

APPLICATION OF ELECTRICITY TO THE DEVELOPMENT OF "DIP" WORKINGS, AND TO OTHER PURPOSES, AT LOGANLEA COLLIERY.

At the last meeting of the Scottish Branch of the Association of Colliery Managers, held in Edinburgh, Mr. Robert Weir, manager, read a very valuable Paper on this subject. The available area of the most valuable seam of coal in the pit, he said, being nearly exhausted to the rise, the proprietor desired to get to the dip where the coal lay virgin. In order to develop the latter an extensive and efficient hauling and pumping plant was necessary; and to proceed on the general lines of the methods most approved of until recently presented difficulties.

Already the electrical transmission of energy had engaged the attention of the mining community, and successful and economic installations were in operation at various collieries; and although the natural conditions of Loganlea colliers, to a great extent, secured immunity for dangers arising from the sparking of the different parts of the machinery, or the breaking of the conductors, still the reluctance to adopt a power whose properties and laws entailed on the colliery engineer special study and experiment, was not overcome until careful observation and inquiry revealed the fact that not only was electricity entirely suited for the development of dip workings, but was pre-eminently a power adaptable to coal-cutting and the driving of fans and other machinery underground and situated long distances from the shaft. To the further application of electricity to these purposes, then, the desired plant was designed and erected.

The surface erection consists of a diagonal engine, having an 18in. cylinder by 30in. stroke, together with a 40-unit compound dynamo, capable of developing a current of 200 amperes at 200 volts when running at 600 revolutions. The cables in the shaft are conveyed from the engine-room switchboard to one similarly equipped underground. The conductors are insulated and protected by a lead cover. The cables are secured in the shaft in pitch-pine casings, suspended from a steel-wire rope.

Digitized by Google

After describing the haulage plane from the dip-end of the pit, the haulage apparatus, drums, gearing, &c., and the composition of the trains, the author went on to say that by means of a rheostat, in conjunction with the break-switch, sufficient resistance could be cut out to increase the periphery speed of the drums from two to four miles per hour, or *vice versâ*. With this haulage it is intended to extend the dip-plane to a distance of 700 yards, and already a length of 180 yards has been won. The drum motor is series-wound, and is capable of working up to 30 H.P. Next in order, the pumping machinery was described in detail, the amount of water to be raised from the pit bottom being about 240 gallons per minute; and the author remarked that a resistance coil is also in use at the pump motor, which is of similar construction to that at the haulage; and the number of strokes may be regulated from 30 to 45. For nearly twelve months this plant has now been in operation and its success fully demonstrated. In some measure this result may be attributed to Mr. William M'Whirter, of the Faraday Electrical Works, Govan, near Glasgow, who designed and erected the whole electrical installation, as before entering upon a contract he thoroughly familiarised himself with the circumstances incidental to mine haulage and pumping and the exigencies likely to demand special contrivances in the construction of dynamo motors.

In contemplating the introduction of new or improved machinery, the first cost is often the only consideration from an economical standpoint, the efficiency and facilities for prospective development being entirely disregarded. At Loganlea it would have been a simple matter to have erected an engine on the surface, and conducted the haulage on the ordinary "dook" method; but already an endless rope from the hill occupied much of the available space set apart for haulage in the shaft, and a complication of ropes was not desirable. Further, the hauling from another seam to the same pit bottom was then a question within practical limits, and about two months ago this was satisfactorily accomplished by the application of electricity to the tail-rope system. In view of these several haulages and the water to be pumped, it was apparent that, even in the matter of first cost, an electrical installation was the most economical, when compared with the expense of the several engines, the pump, and the requisite steam-pipes and fittings. The transmission of power electrically, and the ease with which the current may be subdivided and controlled, offered inducements which have been wholly realised; and to some extent this may be due to the provision of a dynamo, the output of which so far has not been overtaxed.

The first experience of the pump was not so successful as had been desired, for after six weeks' work a perceptible sparking at the commutator increased to intermittent flashes, ultimately burning the insulation of the armature-winding; and on examination of the several parts of the motor no satisfactory reason could be assigned for this. It was then suspected that the vibration of the helical gearing, transmitting, as it did, a lateral motion to the armature, had somewhat loosened the winding, and the continual friction gradually wore away the insulation until a short circuit resulted. To counteract this apparent defect in the helical gearing the pinion on the motor shaft was allowed to slide free, the key being replaced by a feather fitted on the shaft. Thereafter the pump continued to work smoothly for a month, when sparking and flashing were again repeated. It was then resolved to substitute for the helical gearing on the motor and intermediate shafts engine-cut steel wheels of the ordinary description. At this time the experience acquired by the manager suggested the advisability of providing a supplementary armature for the pump, and as the confidence in the one then in use had been shaken, it was resolved to test the new gearing and a second armature on the same occasion. That test was entirely satisfactory, and extended to a period of nine weeks, during which time the pump was only allowed to stand for five minutes in every twelve hours, the number of revolutions of the armature per minute averaging 500.

Next followed some remarks on the desirability of using an electrical governor on the engine of the most approved character, on the calculation of the horse-power expended in mine haulage and pumping, on the computation of the horse-power requisite for the working of the tail-rope haulage, and on the advantages resulting in the development of dip-workings by the use of electricity; and then Mr. Weir proceeded to make some conclusions in the following terms: In none of the industries to which electricity has been successfully introduced within recent years, he said, is the same opportunity presented for general application as in mining, nor do the laws of nature in any other sphere operate with such adverse tendency. The security of life, the safety of the mine, and the efficiency and economy of the different appliances are matters which must alike engage the attention of mine managers and electrical engineers. The dissipation of electrical energy in no way interferes with the ventilation of the mine, though at Loganlea (where each of the motors is placed in the intake air-way) shortly after the installation was in operation, complaints as to vitiated air were numerous; they were, however, purely imaginary.

THE ELECTRICAL TRADES SECTION.

A meeting of the Electrical Trades Section of the London Chamber of Commerce was held on the 2nd inst. at the offices of the Chamber, Botolph House, Eastcheap, under the presidency of Major Flood Page.

The SECRETARY (Mr. Kenric B. Murray) having read the minutes of the last meeting, which were approved by the present meeting,

The CHAIRMAN said he would like to make a few remarks before they went to the matters referred to on the agenda. It was a long time since they had held a meeting of the Section, but although that was the case they had not been idle, for they had had no fewer than thirteen meetings of one description or another since the minutes just read were recorded. He desired to draw their attention to a matter which concerned not only the electrical but all trades—namely, the London Chamber of Arbitration, which had been formed by the London Chamber of Commerce, and the City Corporation. They had now got together about 1,100 arbitrators representing most of the trades in London, and although old contracts which existed, and in which another way was provided for settling disputes, hindered the rapid progress of the Chamber of Arbitration, yet they would be interested to learn that up to April last nine cases had been decided by that body. The average amount of fees paid in these cases had been only £5. 12s., and one amount in dispute was no less than £40.000. He had been requested to draw their attention to the fact that a very simple clause had been agreed upon, and it was the hope of the Chamber of Commerce and of the Corporation that the electrical companies and all who were interested in electrical business would try and get the clause into their contracts, just as all the other trades were doing. The clause was as follows:—"All disputes which may arise relating to this contract shall be submitted to arbitration under the rules for the time being of the London Chamber of Arbitration." He thought it might be claimed for this system that it was expeditious, economical, and efficient, and he commended it to their careful consideration. There was another matter which he had been desired to bring before the meeting. In their business they had happily not yet had many disputes between employers and employed, but there was a London Conciliation Board also in connection with the London Chamber of Commerce. The Board consisted of an equal number of employers and employed, who met on an absolute equality. Mr. Boulton was the Chairman of the Board, which had been meeting for three years, and the results had undoubtedly been very satisfactory, none of the decisions which had been arrived at having been disputed yet by either side. As the electrical industry grew they would probably be more interested in the matter.

Mr. SYDNEY MORSE said he thought it ought to be understood that if the clause which had been read by the Chairman were put into any contract it was absolutely irrevocable.

The CHAIRMAN stated that that was so. The London Chamber of Arbitration was a legal court, and with the clause which he had read put into a contract, no other system of arbitration was open under that contract. With reference to the matters which were to come before them that day, as set out in the agenda, he would not anticipate anything that might be done either in regard to overhead wire regulations or as to the question of traction. They had had many meetings of the Overhead-Wire Committee, and he held in his hand certain private correspondence which had taken place between the Board of Trade and the Institution of Electrical Engineers. He might state that the trade was in a much better position, by reason of the action which had been taken by the Section, than they were a little time ago. It would be very much to the advantage of the Section if they could work with the Institution—if the latter would go as far as they wished. With regard to the question to be brought before them by Mr. Gareke, the principle involved in it was that power was to be sought for the appointment of a Sub-Committee which should not come under the ordinary rules governing the sub-committees of their Section, but that it should be a Sub-Committee with power to raise funds and take such action as might be necessary in the interests of a particular portion of the electrical industry. A separate Association existed already with respect to the supply companies outside their organisation. Most of them, who had been connected with the Electrical Trades Section from the commencement, had always felt that it was a great pity that a number of associations outside the Electrical Trades Section of the London Chamber of Commerce should be formed. They had always felt that if it were possible and consistent with the rules of the Chamber, it would be better that committees should be formed in connection with the Chamber. It had been suggested whether it would be advisable that Papers should be read and discussions take place next winter on purely commercial matters, which were really in the interest of the Section, but were outside the special work of the Institution of Electrical Engineers.

Mr. CROMPTON, referring to the subject of overhead-wire regulations, said he thought there was no doubt that matters had advanced a stage, and that the Board of Trade would ask to have assistance. If not, he thought that the Institution would be entitled to call in the assistance of the Electrical Trades Section to put pressure on the Board to receive a deputation again, and to point out that the existing regulations in connection with their industry were far from perfect in many ways.

General WEBBER said that if the correspondence referred to were circulated among the meeting, the members would be satisfied to find, he thought, that the Board of Trade, while demurring to making any important changes unless the necessity for them were fully established, were quite ready to meet the wishes of the Council of the Institution of Electrical Engineers, and at the same time the Board of Trade knew that it would be meeting the wishes of the Chamber of Commerce. The fundamental points discussed by the Committee of the Section and by the Committee of the Institution had been brought before the Board of Trade in the correspondence. He fully believed with Mr. Crompton that the Board of Trade were quite alive to the importance of certain alterations being made for the benefit of the industry.

On the motion of Mr. GARCKE, seconded by Mr. CROMPTON, it was decided to refer the correspondence to the Overhead-Wires Committee.

The CHAIRMAN stated that the next subject on the agenda was electric traction.

Mr. GARCKE stated that the objects he had in view in proposing the motion, notice of which had been given, were, as the Chairman had said, that the undue multiplication of societies or organisations to deal with electric matters might be prevented, and to enhance the value and the scope of the Electrical Trades Section. The Chairman had already referred so fully to the desirability of those objects that it relieved him of the necessity of saying very much. The only object he had in view in bringing the matter forward was the desirability of merging the organisation which had already been formed into the organisation of the London Chamber of Commerce. They had all probably already heard of the formation of the Electric Traction Association for the purpose of preparing evidence and for other purposes in view of the appointment of a Joint Committee of both Houses of Parliament to deal with traction questions. It had occurred to him that it might be advantageous to the gentlemen who had constituted themselves into that Association to carry out their purposes by means of a sub-committee of the Electrical Trades Section, and he had therefore consulted with Mr. Murray as to whether such a course was practicable and consistent with the organisation of the London Chamber of Commerce. Mr. Murray had informed him—after consulting, he believed, with his Chairman—that it was quite practicable and quite in accord with the rules of the Chamber, and, as the Chairman had explained to them, it only required the passing of a resolution by their Section approving the formation of such a Committee, and the confirmation of the resolution by the Council of the Chamber to complete the arrangement. As the Chairman had pointed out, it was undesirable to have several organisations dealing with the various questions which from time to time cropped up, and if they came into the organisation afforded by the section to deal with such questions, it must be to the advantage of all parties. He believed, altogether, that his proposal would commend itself to the meeting at once. The proposal was as follows:—"That this Section approve of the formation of an electric traction sub-committee, with power to raise funds, engage Counsel, and take such other steps as may be in their opinion necessary for the advocacy or protection of traction interests." It must be in the form of such a committee, in order to enable them to raise funds. That had always been the difficulty that had blocked the way to the formation of such committees—that they had understood that they were not able to raise funds for their own specific purposes; but Mr. Murray had informed him that there was no objection to this, that such a committee would have the right to spend money on objects which were deemed advisable, and that it would not be controlled by the other committees or by the Section. His resolution went on:—"That the following members constitute the sub-committee, with power to add to their number. (Then the names would come in.) Such sub-committee shall be confined to the above members, and to such others as shall be elected by them, provided that no one shall be eligible for election as a member of such sub-committee who is not a member of the London Chamber of Commerce; and the sub-committee shall be subject to the general rules of the Chamber, and shall report from time to time to the Electrical Section."

General WEBBER seconded the resolution.

Mr. GAINE (General Manager of the National Telephone Company) said he would like to ascertain, in the first instance, what the exact object and meaning of such a committee, if appointed, was. He did not think it required very much divination to ascertain what the intention was. They all knew, he thought, that the suggestion was really the formation of a protection committee—to protect one interest as against another interest—which was also represented in the London Chamber of Commerce; that was to say, it really, after all, became a question between the electric traction interest and the telephone interest. He thought it very possible that the railway interest might be affected, but the matter was very much between electric traction and the telephone interest. For a number of Sessions certain clauses had been inserted in certain Acts of Parliament for protecting the telephone interest as against the traction interest, and matters had now come to this point: that a Joint Committee of both Houses of Parliament had been appointed, and would very shortly sit in order to go into the merits of the whole question as between these different interests, and to determine whether the telephone or any other interest was entitled to any protection, and, if so, what protection, and to settle any clauses that might be thought right and proper. As Mr. Garcke had said, there was an Association outside the London Chamber of Commerce for the protection of the traction interest, and what he (the speaker) wanted to know was this: Was the object and intention of the appointment of the proposed committee solely or mainly for the purpose of obtaining the influence and the weight at their back which the name of the London Chamber of Commerce would give them in the inquiry which was to be held. He ventured to say that if that were the object and intention, it was a most improper suggestion, that one interest, represented in the London Chamber of Commerce, should seek to have the weight of the Chamber at its back as against another interest also represented in the Chamber. At any rate, unless it could be clearly shown to be in the public interest, he maintained that there was no ground for such a proposal as that which had been submitted to the meeting. He had looked through the rules and bye-laws which had governed the Chamber, and he could not find anything whatever specific which dealt with the case of conflicting interests; but he did find a provision, as had been pointed out, that no resolution which was passed by a Trades Section was to have any force or effect until it was confirmed by the Council or the Chamber itself. What he wanted to arrive at was, as he had said, whether the sole or main object of the appointment of the proposed committee was for the purpose of obtaining the weight at its back of the name of the London Chamber of Commerce in the conflict which was about to take place before Parliament, and as against another interest which was equally a member of the Chamber; because he reiterated that, in that case, it was, in his opinion, a most improper suggestion to make, and a course of proceeding which he objected to, as a member of the Chamber, in the strongest possible terms, and one which, he ventured to say, the Chamber would be very wrong to take up unless a strong case were shown that it would be right for them to do so in the public interest. There had been no suggestion by the mover of the resolution that any question of public interest was involved in it. If such a suggestion had been made he would have been very glad to have answered it, because he was quite prepared to show that the public interest was quite as much, if not more, on the side of the interest attacked by the resolution as it was on the side of the interest proposing it. As far as he was concerned, on behalf of one very large interest represented in the London Chamber of Commerce, he objected in the strongest possible way to the passing of the resolution.

The CHAIRMAN said he could only state, with respect to Mr. Gaine's question whether it was the intention to have the weight of the Chamber in favour of one Section as against another Section, that it was open to the interest represented by Mr. Gaine to form a similar committee on its own behalf. The proposal was brought forward with the view of really lessening the sharpness and the acuteness of the antagonism. The fight must go on, and the question was should it go on entirely outside without any of the advantages which might accrue from their meeting inside.

Mr. GAINE stated that he did not want to oppose the proposal except on the ground which he had brought forward. A Parliamentary inquiry was about to be held, and he desired to know whether the name of the London Chamber of Commerce would in any way be associated with the traction interest represented before the inquiry.

The SECRETARY said he presumed that the proposed sub committee desired to act only as a Traction Sub-Committee.

Mr. GARCKE: As the Traction Sub-Committee of the London Chamber of Commerce.

Mr. MORSE observed that the fact that Sir Albert Rollit was President of the Chamber and a Director of the National Telephone Company would not give greater weight to his evidence, any more than the fact that they were a sub-committee of a Section of the London Chamber of Commerce would give weight to theirs.

The CHAIRMAN reminded them that when they had met before he had expressed each time the matter had been discussed that their object was to lessen the acuteness of the fight. His view of the matter was that it was not intended, and that it would not be possible for the proposed committee to take any higher position than that they were a sub-committee of the Electrical Trades Section of the London Chamber of Commerce.

Mr. GAINE: Representing a particular interest?

The CHAIRMAN: Representing absolutely a particular interest.

Mr. GARCKE, in answer to a question, said that the proposed resolution had been carefully considered, and he did not think they would be empowered to omit the reference in it to raising funds and engaging counsel. An association had been already formed, and his desire was to prevent the multiplicity of other societies and to consolidate all electrical interests rather than to have them scattered.

Mr. GAINE: The funds of the Chamber are not in any way involved if the resolution is carried?

Mr. GARCKE: No.

The CHAIRMAN stated that he also added the following words at the end of the resolution:—"And in this case the President of the Chamber, the Chairman of the Council, and the Chairman and Vice-Chairman of the Electrical Section shall not be *ex-officio* members of the sub-committee." He then put the resolution, which was carried, Mr. GAINE remarking that he supposed he might be in a minority of one.

Mr. GAINE asked when it would be confirmed.

The SECRETARY: On the 8th.

On the motion of Mr. GARCKE, the following gentlemen were nominated to be the sub-committee, with power to add to their number:—Messrs. Crompton, Morse, Kite, Babcock-Wilcock, Sellon, and Garcke.

The CHAIRMAN stated that the next matter on the agenda was to consider the desirability of representations being made to the Railway Association that a special rate should be granted for the carriage of electrical wire and cable. The question originated in a correspondence that had taken place between Mr. Murray and Messrs. W. T. Glover and Co.

Mr. HENRY EDMUNDS (Messrs. Glover and Co.) stated that they were all suffering with others in regard to the advance of railway rates, and they had no goods that came under the companies' classifications where they could take their own risk as owners, as against the companies' risk. It would be useful if the companies would allow them to have their own risk as owners.

The question was referred to the Railway Rates Committee of the Section.

The CHAIRMAN said he was present at a meeting of the Council a short time ago, when a member of the Council proposed a resolution which he (the Chairman) felt that it was not ripe for them to discuss, and it was therefore referred to the Section.

The SECRETARY read the resolution, which was as follows:—"That in view of the competition of the New Telephone Company having been virtually extinguished by the amalgamation with the National Telephone Company, the commercial interests of the City of London, as concerns the present telephone monopoly, be vigilantly guarded by the Council of the Chamber, and that, further, the Council be requested to draft an amendment to the National Telephone Company's Bill now before Parliament, to insert a clause forbidding any preferential treatment of any subscriber without proper notice to the other subscribers of such preference; such draft amendment to be placed in the hands of the President of the Chamber, with a request that he should move the same at a fitting opportunity."

Digitized by Google

The CHAIRMAN said that the Council had never seen the Bill referred to, nor had he seen it.

Mr. GAINE stated that there was such a Bill, but it was in a state of suspended animation.

General WEBBER said that if he were not mistaken the Post Office licence provided for the protection of the public in the particular matter in question.

On the motion of Mr. MORSE the subject was postponed, and the meeting then terminated.

CORRESPONDENCE.

THE ELECTRO-CHEMICAL EQUIVALENT OF ZINC.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In commenting on the account of some experiments on the electro-chemical equivalent of zinc, which you published in your issue of June 2nd, you remark that the slight film observed on parts of the zinc plates may have been due to impurities in the plates themselves. I should think that this was very likely the case, as, though the anodes, from which the zinc is electrolytically dissolved, were of the material known in commerce as "pure zinc," the cathodes were of ordinary sheet zinc.

It seems worth while to draw attention to the use made of limits in these experiments. Two values, namely, 0·0003391 and 0·0003381, were found; each from a group of three experiments. In one of these groups the electrolyte was slightly acidified so as to give it a very slow solvent action on the plates. In the other group the action of the electrolyte caused a slight gain of weight. Hence it seems that the value given by a solution which had no independent effect on zinc, and which, therefore, should be the true value, must lie between these.

With regard to the atomic weight of zinc, I remember having noticed that the value I had deduced by comparison with copper was within about one-half per cent. of a result given by Dr. Gladstone and Mr. Hibbert in the *Proceedings* of the Chemical Society for 1888, if I remember rightly.—Yours, &c., J. ERSKINE MURRAY.

40, Montgomerie-drive, Glasgow, W., June 4, 1893.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your current issue is a Paper by Mr. Murray on the "Electro-Chemical Equivalent of Zinc," which you remark has a bearing on the atomic weight of zinc. It may, therefore, interest you and your readers to know that some years ago Dr. Gladstone and I determined the atomic weight of zinc by a voltametric method. I enclose a copy of our Paper, from which you will see that there are several points of difference between our method and Mr. Murray's.

Our standard was the silver voltameter. This is acknowledged to be more accurate than copper sulphate as commonly used, though Mr. Gray has shown how to get the very best results with it.

Our mean ratio for the equivalents of silver and zinc was 3·298 to 1, which gives 0·0003389 as the electro-chemical equivalent of zinc per ampere per second.

This is very close to the mean of 0·0003386 given by Mr. Murray. But I think that gentleman will acknowledge that the true value is probably nearer that obtained with neutral solutions of the zinc sulphates. Indeed, this is shown by the figures given in Mr. Murray's Paper for the loss sustained by zinc when standing in the neutral and acid liquids.

I therefore suggest that Mr. Murray ought to allow greater weight to the higher of the two values he obtained. Let that result be given a weight twice as great as the other, and the true mean becomes 0·00033877.

This is still nearer our value, the difference being only 1 in 2,500.

Another point of interest may be noted. Our method was to compare the amount of zinc dissolved at the anode with the amount of silver deposited. As the result obtained by Mr. Murray for deposited zinc agrees so well with ours for the zinc dissolved *at the other side of the voltameter*, the two results form an admirable illustration of the equivalence of the chemical action at the two electrodes.

I reserve some remarks on the atomic weight for another place.—Yours, &c., W. HIBBERT.

14, Goldhurst-terrace East, N.W., June 6, 1893.

THE TESTS OF A LARGE "CASTLE" DYNAMO.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: On page 114 of your last issue you make some interesting remarks on temperature tests of dynamos occasioned by a rather great difference between the rise of temperature given for Messrs. J. H. Holmes's dynamo (illustrated in the previous number of *The Electrician*), as obtained from two independent tests, Prof. Kennedy's figure being 72, and that printed under my name 44·7° F. Will you kindly allow me to state that I cannot take the responsibility for the latter figure. The armature temperature at the end of the run was 57° C., that of the engine-room 26·5° C, the difference, 30·5° C., *i.e.*, 54·9° F. is the figure, which I would call the rise of temperature *of the armature bars*; but the greatest temperature rise, which I found in the armature is 72·9° F. The 44·7, you will see, refers to the rise of temperature of the armature itself, irrespective to a certain extent of the surrounding atmosphere, and is, as far as I can see, of no interest whatever. It was not suggested by me.

The temperature rise of 72·9° F. was measured in the winding across the ends of the drum, that of 54·9 on the outside of the cylinder formed of the bars. The latter is representative of the type of the dynamo depending on the kind of armature-bars and the kind of core used in the machine. The higher figure, the 72·9°, being the rise in the end-winding, where there are no eddy currents to cause a rise of temperature, depends mainly on the amount of draught admitted to the spirals of strips of which this winding consists. In the present machine, with its heavy insulation, the draught was small. I have no doubt that a little attention to this point, on the part of the makers, will enable them to get the maximum rise in this type of machine down to that given above for the armature bars, *i.e.*, to about 55° F.

You also compare the steam consumption in the engine, which is, according to Prof. Kennedy, 20·3lb., by my own test 21·66lb. per electrical horse-power hour. I would like to say that the difference is accounted for, I believe, by an earlier cut-off being used in Prof. Kennedy's test than in my own, which was a preliminary one.—Yours, &c., F. V. ANDERSEN.

PHYSICS AND METAPHYSICS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your most interesting leader on the above subject, you have challenged metaphysicians to say whether physics can gain anything by going behind the scenes into metaphysics. Far be it from me to seem to accept the challenge, for I have never been lured very far into the tangled waste and weedy ground of metaphysics; but it occurs to me that your readers may like to have a note or two, culled from authors of acknowledged fame. Firstly, the genius of Kant—that star of the first magnitude—attracts us; and we find him telling us "*that those who engage in metaphysical pursuits are far from being able to agree among themselves, but that, on the contrary, this science appears to furnish an arena specially adapted for the display of skill or the exercise of strength in mock contests—a field in which no combatant ever yet succeeded in gaining an inch of ground—in which, at least, no victory was ever yet crowned with permanent possession.*"* The history of metaphysics, both before and since the time of Kant, establishes this grave indictment. Clerk Maxwell says: "*I would advise those who study any system of metaphysics to examine carefully that part of it which deals with physical ideas.*"† It is clear that Maxwell was in the habit of testing his metaphysics by his physics, instead of *vice versâ*.

When we hear that there is a Guy-Fawkes-like attempt to blow up the foundations of a deductive science like dynamics, it is time to see whether it is really a gunpowder plot, or if,

* "Critique of Pure Reason."—I. Kant.

† "Matter and Motion."—Clerk Maxwell.

Digitized by Google

perchance, there may not be only dust in the bags instead of powder. If, as is reported, Prof. Lodge asserts that the notion of action at a distance is, *à priori*, as tenable as that of action through a medium, he does so, not in virtue of, but in direct defiance of the recognised systems of metaphysics. However they may disagree, those systems are agreed that the *à priori* is that which is absolutely necessary to thought, as contrasted to the *à posteriori*, or that which is imposed on thought—empirically—by acquired experience. Now, to assert that the human mind might be able to subject itself logically to an objective world in which action at a distance might be possible, would be equivalent to saying that the human mind is capable of cognising a causeless phenomenon, or an event without any contiguous impulse to produce it; which is manifestly incorrect. The notions of contiguous action, of the conditions implied by Newton's first and second laws, and the idea of force expressed by the second law, are not *mere* matters of experience; they are apodeictic necessities, and proceed from the inability of the mind to evolve any idea of a self-producing phenomenon in space and time. The very ether is only to be believed in because the human mind is incapable of conceiving of stress, propagation, retardation, &c.—in a word, *force*—apart from a material medium. Deny Newton's laws, and one may have a moving body retarded without anything to retard it; one may have light refracted without any ether to refract it; one may have any amount of interesting *phenomenon* in the universe without any cause whatever! But one cannot deny Newton's laws; it is logically impossible—only a sophist like Zeno could deny them. Not because the laws are established by experience (for they are *not*), but because the truth of them proceeds from the very pith and marrow of one's inner consciousness. Rather than deny these laws every physicist would invent any number of complicated ethers!

Referring briefly to another point, it seems to me that your definition of an axiom as "concept based on experience" must include all *à posteriori* concepts under the class of axioms, making all inductive knowledge axiomatic. It is experience that tells one that potassium and sulphuric acid evolve hydrogen; and a number of such experiences may evolve the concept that potassium and an acid will evolve hydrogen. But this concept would, I think, scarcely bear elevation to the dignity of a chemical axiom. The definition of an axiom is one of the most difficult to make—perhaps it is axiomatic! Lotze defines an axiom as an "immediate truth;" and Kant as "a synthetical judgment *à priori*;" but neither of these gets over the difficulty that what is an axiom in A.D. 1600 is "bosh" in A.D. 1893.—Yours, &c.,

E. TREMLETT CARTER.

June 2, 1893.

USEFUL FORMULÆ, &c.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: For those who wish to have an idea of the watts per pound a machine gives, knowing the output in kilowatts or units, and weight in cwts., the following rule will, I think, prove acceptable.

Rule.—Nine times the number of units per cwt. will give the number of watts per pound. So that 1 unit per cwt. signifies 9 watts per pound. This is correct within less than 1·25 per cent.—Yours, &c.,

ARTHUR F. GUY.

June 1, 1893.

"THE ENGINEERING MAGAZINE."—The June issue of the *Engineering Magazine* (which can be obtained at the offices of *The Electrician*) contains articles of interest to the electrical and engineering professions, amongst which are the following:—"Great Britain at the World's Fair," by Mr. James Dredge; "The Latest and Greatest Cunarder"; "Evolution of the Ironfounder's Art," by Mr. S. Bolland; "The Trans-Siberian Railway," by Mr. F. Hobart; "The American Passenger Elevator," by Mr. T. E. Brown; "Fire Risks in Electric Insulation," by Prof. Perrine. The articles by Mr. W. M. Acworth on "English and American Railways," and by Prof. Thurston on "Progress in Steam-Engineering," are continued; and many articles of general public interest are included.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week*]

TENDERS INVITED.—The Corporation of Bury (Lancs.), invite tenders for electric lighting plant, which are to be in by July 15th.

——— Tenders are required for the lighting and maintenance of the public street lamps of Plympton St. Mary and Plympton Maurice (Devon), from September, 1893, to April, 1894, and must be in by the 17th inst.

——— Our readers are reminded that the tenders for electric cables, conduits, feeding boxes, &c., for the Urban Sanitary Authority of Portsmouth, have to be in by 10 a.m. on the 23rd inst.

——— The Council of the city of Worcester invite tenders for the erection of their electric lighting station and buildings at Powick Mills, near Worcester. Tenders have to be in not later than the 24th inst.

TENDERS ACCEPTED.—The Ealing Local Board have adopted the recommendation of the experts appointed by the Board in connection with the electric lighting scheme, and have accepted the tender of Messrs. Watts and Co. for the construction of boilers and machinery at the Southern Sewage Works.

——— The tender of Messrs. Allen and Co. has been accepted for the erection of the electric lighting station for the Kingston-on-Thames Town Council, for the sum of £3,656.

——— As stated in our issue of May 19th, the tenders of Messrs. Horsfield (Dewsbury), Messrs. Crompton and Co., Limited (London), and Messrs. Siemens Bros. and Co., Limited (London), have been accepted for electric light and plant for this borough. The amounts are as follows:—

Messrs. Crompton and Co. (Limited), for engines, dynamos, switch-boards, accumulators, &c.	£6,257
Messrs. Siemens Bros. and Co. (Limited), for mains	3,856
Messrs. J. and J. Horsfield, for boilers	2,998

APPOINTMENTS.—Mr. Proctor, who has been acting as clerk of the works for the erection of the Bristol Central Station, has been appointed Resident Engineer at a salary of £260 per annum; and out of 40 applicants Mr. A. W. Rankin had been appointed Assistant Engineer at a salary of £130 per annum.

——— Mr. A. E. Farrow has been appointed resident engineer for the Windsor Electric Lighting Company; and has already taken over the charge of the works in Goswell-lane.

PERSONAL.—Mr. Reginald J. Wallis-Jones has joined the staff of Messrs. Kincaid, Waller, and Manville, consulting engineers.

RESIGNATION.—The *Richmond Herald* states that Mr. Shoolbred, electrical engineer to the Richmond Town Council, has tendered his resignation.

REMOVAL.—The Glasgow branch of the General Electric Company has been removed from 79, West Regent-street, to 196, St. Vincent-street.

BANKRUPTCY.—William McWhirter, electrical engineer, of Campbell-street, Govan, Glasgow, was adjudicated a bankrupt on May 30th. Creditors are to meet in the Faculty Hall, Glasgow, this day (Friday) at 12.

MESSRS. BOURNE AND GRANT.—We are asked to insert the following:—"As some misapprehension appears to exist in consequence of the registration of the Bourne and Grant Electricity Supply Company (Limited), may we ask you to be good enough to allow us to state that the business of electrical engineers and contractors hitherto carried on by us is in nowise interfered with or altered by the creation of the Company, which is a distinct and separate concern."

DIRECT UNITED STATES CABLE COMPANY (LIMITED). A branch station has been established in Winchester House by this Company for the transmission of messages to and from North and South America. The new station is situated on the first floor, and is in direct communication with the Company's cables.

FIRE.—On Sunday a destructive fire occurred at the engineering works of Messrs. Alley and M'Lellan, Polmadie, Glasgow. The loss is estimated at about £10,000, which is covered by insurance.

MESSRS. NEW AND MAYNE'S TRANSFORMER SWITCH.—We have received a sketch and description of an automatic switch for cutting a transformer out of circuit when the last lamp is switched off the secondary, and for putting in again when a lamp is turned on. The apparatus appears on the sketch to be exceedingly complicated, but this is not necessarily a disadvantage. It consists of main switches on both secondary and primary circuits, the latter being provided with a spark-breaking shutter. Two trains of clockwork and three solenoids, besides an electromagnet, numerous contact pieces, and resistance coils are provided. When a lamp is switched on, the apparatus is so disposed that a primary battery sends a current

Digitized by Google

through the distributing leads, and, by means of a magnet, works a train of clockwork, and pulls over a weighted lever which works the main switches and other contacts. The last lamp being turned off, a solenoid starts the other clockwork, which turns off the switches. We understand that the apparatus has been tried and found to work.

THE EDISON-SWAN COMPANY.—This Company are now in a position to undertake at their works in London, silver-plating, nickel-plating, and gilding of all descriptions.

TELEPHONES.—Mr. Kotyra, the agent in Great Britain for Messrs. Ch. Mildé and Co., has just issued a handy catalogue illustrating a large number of telephones and telephone accessories, for which the firm have for many years been celebrated. The illustrations include 31 different patterns, all of which are either patented or registered. It is claimed that the instruments are all of high-class workmanship, and specially suitable for the home and colonial markets. On page 21 a useful form of telephone "inkstand" is shown, and on page 20 a portable table combination. On page 22 is shown a telephone inkstand in highly-finished artistic brass work, and on page 23 the "manipulator" on a curved wood stand with switch and connecting plate. In addition, illustrations of trembling bells, indicators, tools, and pot cells are shown. The list can be obtained by the trade on application at the London office, 60, Watling-street, E.C.

THE PHOSPHOR BRONZE COMPANY.—We have received from this Company their new catalogue of phosphor bronze specialities. The list includes a number of illustrations, showing a variety of uses to which the Company's manufactures are specially adapted. A number of testimonials are included in the list, and several useful tables. Among the illustrations is one of a second-class torpedo boat, built entirely of rolled and drawn phosphor bronze plates and angles.

MESSRS WILCOX AND CO.—At all the principal agricultural shows throughout the country, including Chester, Norwich, and Tunbridge Wells, this firm are exhibiting a great variety of engineering specialities, for which they are well known throughout the trade, including packings, oils, engine and boiler mountings, hose, lubricators, belts, and an enormous variety of engineers' tools and general stores, specially suitable for employers of steam power.

ELECTRIC LIGHTING CONTRACT FOR RUSSIA.—Messrs. Mavor and Coulson have recently concluded a contract for electric lighting on a large scale in Russia. The place to be lighted is a woollen factory near St. Petersburg, the largest establishment of the kind in the country. About 6,000 16-c.p. lamps will be required, and the contract includes everything needed for the installation.

ABERDEEN.—The Gas Committee of the Town Council recommend the appointment of an Electrical Engineer at a salary of £200 per annum. It was decided that the Electrical Engineer should be under the superintendence of the Gas Manager.——The Directors of the Northern Co-operative Company have finally decided to introduce the electric light into their premises at Loch-street, and the Buildings Committee have the matter in hand.

BEDFORD.—The Urban Sanitary Authority have had under discussion the question of the tenders recently received for the electric lighting scheme. A complaint having been made by a member of the Board that these tenders had not been distributed amongst the members, a resolution was proposed asking that this should be done, accompanied by a report of the sub-Committee who had been appointed to inquire into the matter; but the matter fell through.

BELFAST.—The works in connection with the extensive installation of the electric light along the Queen's Quay are being rapidly pushed forward. The engines for the station are to be supplied and fixed by Messrs. Combe, Barbour, and Combe, and are to be fitted with Corliss valves. They are of sufficient power to drive a plant largely in excess of that at present being put down. The area of lighting is from the Queen's Bridge, along the Quay, round the Abercorn Basin, and on both sides of the Hamilton Graving Dock. Thirty-one are lamps of 2,000 c.p. are to be erected. Some difficulty has been experienced in placing the lamps, in order not to interfere with the traffic, or the loading and unloading of vessels, but the difficulties have now been overcome. Messrs. Siemens Bros. and Co. are the contractors for the work, and will also supply the lamps. In addition to the lighting of the quay, the Harbour Commissioners contemplate putting down an underground circuit for supplying incandescent lights on hire for vessels in the docks. Mr. George Combe, of Belfast, has charge of the electrical work, and Messrs. Giles and Kelly, the Harbour Commissioners' engineers, are superintending the erection of the engine-house and station.——Messrs. D. and G. Graham, of Glasgow, have just completed a large installation at the Grand Central Hotel, which was open to the public on Thursday last, and is one of the largest in the kingdom. The work has been done to the specification of Mr. J. H. Greenhill. The plant consists of two horizontal engines of 100 H.P. by Messrs. Sharpe, and two Galloway boilers of the same horse-power, and two compound-wound dynamos, each capable of supplying current for nearly 600 16-c.p. lamps. The total number of lamps is about 700, including four 1,500-c.p. arc lamps for the dining-room, which are in addition to four 6-light electroliers.

BRISTOL.—The Bristol Industrial and Fine Arts Exhibition, which it is proposed to open on August 28th, is now sufficiently forward in construction to allow of space being apportioned to intending exhibitors. Already a large area has been allotted, exceeding 12,000ft. Plans for the Industrial section of the Exhibition have been adopted, and considerable patronage is promised from local manufacturers and tradesmen. The building is to be lighted throughout by electricity, which is to be made a special feature. The fountain in the Fine Arts section is to be illuminated, and a search-light will be fixed on the front tower. At a meeting of the Electrical Committee of the Bristol Corporation a communication was received from the contractors for the building of the central station asking for an extra allowance in consequence of unpleasant difficulties encountered in laying the foundations. The Committee declined to receive the application. Mr. Preece stated that the works were well in hand, and would, he expected, be completed within three months. A question of lighting the Exhibition buildings was discussed, and the Committee were asked to undertake special lighting in the Fine Arts Department to illustrate the variety of the uses to which current can be applied. It was suggested that the principal electrical engineering firms would willingly participate in such an Exhibition, and the suggestion is to be discussed at an early meeting of the Committee.

CHELMSFORD.—The Town Council contemplate lighting the Shire Hall by electricity, and have asked the permission of the County Council for this purpose.

DOLGELLY.—We are asked by Messrs. A. Hall and Co. to state that the amount claimed by the Dolgelly Electric Light Company for damage to their lamps, claimed from the Local Board, is only a small amount, and that the Board did not refuse to pay this, but simply postponed their decision pending inquiry.

DUNDEE.—A statement has been issued by the Dundee Gas Commissioners showing the financial position of the electricity department. £20,000 has been borrowed, and there is a balance on loan capital of £10,000. The amount of £22,793. 19s. 4d. has been expended in connection with the works. Discussing these accounts, Mr. A. Brownlee, on behalf of the Committee, stated that the electric lighting installation was completed with the exception of the fittings, which had not yet come to hand.

FOREIGN OFFICE.—On Saturday last, the occasion of the public celebration of the Queen's Birthday, the Foreign Office was lighted by electricity. The crowd was very great, but notwithstanding this no inconvenience was experienced from the heat, as has previously been the case.

GLASGOW.—Amongst the recent contracts for electric lighting completed by Messrs. Anderson and Munro is the Western Club Buildings, where lamps of 200, 150, 32, 16, and 8 c.p. are included in the installation.

HACKNEY.—At the last meeting of the Board of Works, a report was presented by the Electric Lighting Committee notifiying that all the necessary Parliamentary notices and plans in connection with the Provisional Order had been prepared and submitted.

HANLEY.—Mr. Joseph Lobley, the Borough Engineer and Surveyor of Hanley, Staffs., has issued his report on the schemes for public street lighting within the compulsory area, accompanied by a short description of the works. The report is published in pamphlet form, and contains interesting details of the progress made with the work since the Provisional Order was obtained in 1891. In September, 1892, the Hanley Council accepted the tender of the Brush Company, amounting to £15 760. The site for the electricity works is conveniently situated near the centre of the area of supply and adjoining the canal, enabling the Council to obtain the necessary coal and water supplies on economical terms. A contract has been entered into for the erection of the necessary buildings for £2,990; with Messrs. John Warner for a 7-ton travelling crane; and with Mr. T. Cass, of Bolton, for three Lancashire boilers fitted with mechanical stokers.

HULL.—At the last meeting of the Electric Lighting Committee of the Corporation, Mr. F. Harman Lewis (who has just been appointed electrical engineer at Wolverhampton) tendered his resignation, which was accepted. It was agreed that advertisements should be issued for a successor to Mr. Lewis, at a salary of £270 per annum.

KELVINSIDE (GLASGOW). The applications for current from the Kelvinside Electric Light Company's mains represent about 4,000 lamps of 8 c.p. each, and already the question of putting down additional plant is being considered by the Directors. It is expected that two engines of about 120 H.P. each will be running in the

Digitized by Google

course of a week or two. A number of large mansions in Kelvinside have been wired for some months, and are still awaiting current, and further wiring is in progress.

MADRAS.—It is stated that, owing to the severe conditions imposed by the Telegraph Department of the Government of India, the Directors of the Madras Electric Tramways Company have decided to adopt the conduit system, in lieu of the overhead system, for their tramways.

NANNERCH (WALES).—Messrs. Paterson and Cooper have just put down a large electrical plant at Penbedw Hall for lighting, motive-power, and heating. The installation consists of about 300 incandescent lamps distributed over the mansion, the stables, coach-houses, sheds, workshops, and cottages, covering about 30 acres. Eight motors are used for working the threshing machines, corn crushers, circular saws, sewing machines, &c., and the heating arrangements are adapted for use in the kitchens and dining-room. The plant includes a Brotherhood vertical compound engine, a Cochrane vertical tubular boiler, and a set of 108 L31 type E.P.S. accumulators. The work, which includes a complete system of electric bells and automatic calls, has been carried out under the superintendence of Mr. A. Marsden.

NEWPORT (MON.).—Alderman Davies, at the last meeting of the County Council, presented the report of the Parliamentary Committee, showing the steps taken to provide electric lighting for the borough. Prof. Robinson had sent in an amended estimate, showing a reduction of £5,000 on the previous figures. He stated that the Provisional Order expired this year, but the Committee were taking steps to secure the light being retained in the hands of the Corporation. The Council approved of the Committee's report.

ROCHDALE.—The Town Council, on the recommendation of the Health Committee, have accepted the tender of Messrs. Laing, Wharton, and Down, for the supply and fixing of the plant required for lighting the Sanitary Manure Works by electricity.

RUGBY.—With reference to a note which appeared in our last issue, we are asked by Mr. J. A. McMullen to say that the question of lighting at Rugby School has been definitely settled, and that on Wednesday, last week, the site for the generating station, situated behind the gymnasium, was approved.

ST. PANCRAS (LONDON, N.W.).—A report has been issued jointly by the Electricity and Public Lighting and Special Dusting Committees of the Vestry on the subject of combining the destruction of refuse with the production of electricity. The report states that there are many instances where waste heat from destructors has been economically used for generating electricity, and that the business of combining the two operations is being entered upon by many of the Local Authorities throughout the country. The Vestry's King's-road Station enables these operations to be carried out advantageously, as a demand exists for electricity in the immediate neighbourhood; and there is no doubt the station would at once take up the whole of the day load and the entire supply of the High-street district, together with 300 Clearing House lights, making 1,800 lights in all, which would be taken from the Stanhope-street station at once, enabling the latter to supply 1,800 further lights in its own district. The report recommends the scheme generally, and the Committees agree that the principle should be adopted. At the last meeting of the Vestry the report was discussed, and the debate upon it was adjourned until Wednesday next.

STAFFORD.—The Town Council have received a report from Mr. Bell, the manager of their gas enterprise, giving details and estimates of a scheme for electric lighting. The Electric Lighting Committee recommend the employment of an electrical expert to report upon the scheme to the Council, and this recommendation has been adopted.

TAMPERING WITH TELEGRAPH WIRES.—On the Derby-day two wires, the property of the Column Printing Telegraph Syndicate, were maliciously tampered with in London with the apparent object of preventing the Company's subscribers receiving the result of the Derby. A reward of £20 is offered for information leading to the conviction of the offenders, and it is pointed out that by the Telegraph Act, 1868, persons tampering with telegraph wires are liable to a term of imprisonment with hard labour.

THE ELECTRIC LIGHT IN MINES. The electric light is to be used in the Roodepoort Deep Level (South Africa)in order that continuous sinking may go on under the best conditions.

THE ROYAL UNITED SERVICE INSTITUTION.—The electric lighting of the large main building of this Institution, as well as of the temporary premises and marquees, has been carried out, to the plans and specifications of Mr. E. Wingfield Bowles, C.E., the consulting engineer, by the General Electric Power and Traction Company (Limited). The main hall is lighted by four large suspended pendants, each carrying five 100-c.p. lamps. Under the galleries pendants are fixed, carrying three lights, and on the gallery itself brass standards are used, each carrying three lights. The total actual candle-power for the main hall is 3,540, and for the temporary lighting 250 16-c.p. lamps are used.

TUNBRIDGE WELLS.—A meeting of the Ratepayers' and Owners' Property Association has been held, and a discussion ensued on the electric lighting question, introduced by Mr. Alderman Clifford, who hoped the town would carry out the Provisional Order they had obtained. He stated that, in response to circulars sent out, there had been already promised something like 1,500 lamps. He thought it would be unwise for the Town Council to hand over their rights to a private company. Another speaker (Councillor Putland) believed that if steps were not immediately taken, the local gas company would probably endeavour to obtain powers to introduce the light. Ultimately it was resolved to discuss the question again at the next monthly meeting.

WINDERMERE.—At Troutbeck Bridge an electric light plant has been put down by Messrs. Fell and Sons. A 27in. turbine is used, together with an Armington and Sims engine and Galloway boiler. A Mordey alternator generates the current. About 650 lamps are already connected.

WREXHAM.—At a recent meeting of the Lighting Committee of the Town Council the arrangement proposed by the Brush Company with reference to the Council's taking over the Provisional Order and powers of the Wrexham and District Electric Light Company was discussed. This arrangement includes the payment to the Wrexham Company of £500 for their rights, and the Brush Company undertakes to provide and construct the necessary station and works (other than actually in connection) within the compulsory area, and to transfer the works and plant to the Corporation, for £13,049. At the meeting, Mr. Paris, acting for the Brush Company, produced the various plans and specifications, and explained the system recommended for the installation, which he estimated would cost for maintenance about £1,200 per annum. A proposal to adjourn the discussion of the subject having been carried, a meeting was subsequently held (May 24th), at which a resolution was proposed recommending the Council not to proceed further with the negotiations. This was rejected, and the Committee recommended the purchase of a pamphlet by Mr. J. A. McMullen, for distribution amongst the members of the Committee. The matter will be again discussed at the next meeting of the Council.

WORCESTER.—It has been decided by the Guardians to invite estimates from three different companies for the supply of the electric light fittings required at the workhouse for the installation which is to be put down.

COMPANIES' MEETINGS.

Elmore's Foreign and Colonial Patent Copper Depositing Company (Limited).

The fourth annual ordinary general meeting of this Company was held at the Cannon-street Hotel yesterday, Mr. F. L. Rawson presiding.

The CHAIRMAN said that the balance-sheet set out in detail the state of affairs. They would find a heading "Liabilities on securities of this Company in connection with loans to Elmore's French Company, £69,274. 18s." This was no money liability, but meant that these investments, which had been lent to the French Elmore Company for them to raise money upon, were out of their hands, and, if the French Elmore Company never paid a penny to any creditor, would be lost, unless they found a sum a little under £10,000 to redeem them. Part of these securities would probably be returned almost immediately; some later on. There was also another liability of £2,500, shown in the balance-sheet, upon the bills receivable discounted, for which the French Company were also primarily responsible. This liability he believed they had got rid of. With regard to the profit and loss account, the expenses were less than in previous years, being in all £2,924. 17s. 6d., as against £3,698 and £7,568 respectively. The balance of the profit and loss (£224,000) they must not assume was all profit, as the shares and debentures of the subsidiary companies were taken at par, and until the price of the shares of the subsidiary companies had risen, it could be merely treated as a balance. With regard to their interests in the French Elmore Company he hoped they would reap substantial benefit from the arrangements which had been come to, the terms of which were set out in the Directors' report (*see* page 163 of this issue). The Directors had been blamed by those interested in the French Elmore Company for not being more compliant in the matter of the settlement; but now that the position of the French Elmore Company was saved, he did not see why the Foreign Elmore Company should abate their rights one iota more than sufficient to enable the scheme to go through. On the other hand, the priority shareholders of this Company blamed them for having helped the French Company at all. In this case success had justified the Directors' policy. The success of the French Company, in addition to being of great value to the American Elmore Company, and to this Company also, would enable them to sell the Belgian and Italian patents, and they still had the patents for India and the Colonies, Russia, and other countries to dispose of

Digitized by Google

NEW COMPANIES, STATUTORY RETURNS, &c.

BENHAM AND FROUD (LIMITED).—The annual return of this Company, made up to May 10th, recently filed, shows that 2,907 out of 5,000 shares of £10 each have been taken up, and the full amount called thereon. The calls paid amount to £28,887. 10s., while £182. 10s. remains unpaid.

BIRMINGHAM HOUSE-TO-HOUSE ELECTRICITY COMPANY (LIMITED). MIDLAND HOUSE-TO-HOUSE ELECTRICITY COMPANY (LIMITED). NORTHERN HOUSE-TO-HOUSE ELECTRICITY COMPANY (LIMITED). The annual returns of the above-named Companies, made up to January, 1893, have recently been filed. In each case the nominal capital is £100,000, divided into 19,900 ordinary and 100 founders' shares, the latter being issued to the parent Company, the House-to-House Company, of Richmond-road, London, S.W. In addition to these shares, the only ones taken are those subscribed for by the signatories to the Memorandum of Association, no calls being paid thereon.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).—The annual return of the Company, made up to May 17th, has been filed. The whole nominal capital of £1,300,000, in £10 shares, has been taken up, the full amount called, and the full amount paid.

ELMORE'S FOREIGN AND COLONIAL PATENT COPPER DEPOSITING COMPANY (LIMITED.).—The report states:—"The surplus for the year amounts to £224,083. 11s. 6d., after payment of all expenses and deducting £30,000 as the original value of the American and Canadian patents, sold in the course of last year. It will be noted that, as in the previous balance-sheet, all the shares and debentures are taken at par, it being impossible to judge of their real value at the present time. During the past year there have been various negotiations with regard to the sale of patents; but it has been impossible to conclude sales on terms that were at all advantageous to this Company, as none of the subsidiary companies were, until lately, in a position to show continuous working on a reasonably large scale. The Directors have pleasure in pointing out that their previous statements in regard to the successful practicability of the Elmore process are now borne out by the results of recent investigations and reports made by various experts, and by committees of the shareholders of the English and French companies."

LONDON PLATINO-BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The annual return of this Company, made up to May 16th, has been filed, 37,548 shares of £10 each (out of a total of 40,000) have been taken up, the full amount called, and all calls (£375,480) paid. 800 shares have been forfeited.

MAQUAY SYNDICATE (LIMITED).—Claims against this syndicate (in liquidation) must be sent in to the liquidator, Mr. T. Rawlins, 45, King William-street, E.C., by July 8th. A first and final dividend will, we understand, shortly be announced.

METROPOLITAN ELECTRIC SUPPLY COMPANY (LIMITED).—The annual return of this Company, made up to May 5th and recently filed, shows that the whole nominal capital of £500,000, divided into 49,900 ordinary shares of £10 each, and 100 founders' shares of like value, has been taken up. 2,132 shares have been issued as fully paid, while the full amounts have been called on the remaining 47,868 shares. The calls paid amount to £478,421. 9s., while £258. 11s. is as yet unpaid.

MEXICAN GAS AND ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return of this Company, made up to November 9, 1892, and recently filed, shows that the whole nominal capital of £100,000, in £20 shares, has been issued as fully paid to Alban G. H. and Herbert C. Gibbs, of 15, Bishopsgate-street Within, London, E.C. (4,993 jointly), and their seven nominees.

MOUNTAIN'S WIRE MANUFACTURING COMPANY (LIMITED).—The first meeting of creditors of this Company (being wound up) will be held at the offices of the Official Receiver, St. Andrew's-chambers, 22, Park-row, Leeds, on Wednesday next, at 11 a.m., and the first meeting of contributories will be held at the same place on the same day at noon.

NEW ZEALAND ELECTRICAL SYNDICATE (LIMITED).—The annual return of this Company, made up to November 11, 1892, has recently been filed. Out of a nominal capital of £30,000 in £10 shares 2,955 shares have been taken up, of which 200 were issued as fully paid to the Gülcher (New) Electric Light and Power Company (Limited). Upon the remaining 955 shares the full amount has been called. The calls paid amount to £6,350, leaving £3,200 in arrears.

YORKSHIRE HOUSE-TO-HOUSE ELECTRICITY COMPANY (LIMITED).—The annual return of this Company, made up to May 26th, has been filed. Out of 19,900 ordinary and 100 founders' shares of £5 each, 7,328 ordinary and 100 founders' shares have been taken up, of which the founders' shares have been issued as fully paid to the promoting company, the House-to-House Electric Light Supply Company (Limited). Upon the 7,328 ordinary shares a call of £4. 10s. per share has been made, resulting in the payment of £32,530, and leaving £592. 10s. unpaid.

CITY NOTES, &c.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended June 4th were £914, as against £782 for the corresponding period of last year, being an increase of £132. The total receipts for the half-year amount to £19,493, against £17,869 in the corresponding period of 1892, being an increase of £1,624.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the month of May are £3,700, as compared with £3,672 in the corresponding month of last year.

DIRECT SPANISH TELEGRAPH COMPANY.—The gross receipts for the month of May were £1,866, as compared with £2,132 for the corresponding period of last year.

EASTERN TELEGRAPH COMPANY (LIMITED).—In our last number we gave particulars of the issue by the Eastern Telegraph Company of £200,000 £4 per Cent. Registered Mortgage Debentures (Mauritius Subsidy) of the Eastern and South African Telegraph Company (Limited). We learn that this issue, the subscription for which closed on Wednesday last, has been subscribed more than twice over.——The traffic receipts of this Company for the month of May amounted to £57,946, and to £54,842 in the corresponding period of 1892, an increase of £3,104.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of the Eastern Extension, Australasia and China Telegraph Company (Limited) for the month of May, 1893, amounted to £45,395 and to £40,612 in the corresponding period of 1892; increase, £4,783.

ELECTRIC AND GENERAL INVESTMENT COMPANY (LIMITED).—The Directors recommend the payment on July 1st next of the following dividends:—On the ordinary shares at the rate of 30 per cent. per annum on the capital paid up for the six months ended May 31st last, making, with the interim dividend already paid, 25 per cent. for the year; and on the founders' shares £30 per share.

ELMORE'S FRENCH COPPER DEPOSITING COMPANY (LIMITED).—Mr. Justice Vaughan Williams on Wednesday pronounced a compulsory winding-up order against this Company; but subsequently, it appearing that the petition had been made in the belief that it was unopposed, withdrew the order, and directed the petition to stand over, with a view to arrangements said to be for the benefit of the creditors being arrived at.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this Company for May amounted to £24,000, and from January 1st to May 31st to £108,000. In the corresponding months of 1892 and 1891 the amounts were £104,800 and £114,000 respectively.

MALTA AND MEDITERRANEAN GAS COMPANY.—Speaking at the ordinary general meeting of this Company, held on Tuesday last, the Chairman (Mr. John Birch Paddon) referred to the increased cost of coal and the decreased price of residuals, and the competition of electric light. He said that "with regard to the competition of the electric light I think that it may be said that, so far, it has done us no harm whatever, but inasmuch as there may be some competition, I think it right to mention two reasons why such competition can have no very great importance. In the first place there is this, that the cost of the electric light in Malta is quite three times that of gas, and consequently the persons who use the electric light there will be the persons to whom the cost is a matter of no importance, and there are not many such persons in Malta. Then the next thing is that there are no known ways of satisfying the consumer of the electric light that he is receiving the volume of light for which he has to pay. Now, thrifty people like to get the full value for their money, and the Maltese people are thrifty in the best sense of the word. Until some reduction in the cost of the electric light is effected, so as to bring it down to the cost of gas—and it is worth no more—and until some approach is made for commercially regulating the measuring of the electric light, I think that we may consider anything like permanent competition from it is out of the question, and whatever installations may be put up will only be a temporary detriment to the gas companies. As regards public electric lighting in Malta, application has been made to the Council of the Government to establish an installation for electric lighting, but the elected members of the Council are adverse to any expenditure of any part of their funds in speculative purposes, and therefore nothing whatever has been done."

MORGAN CRUCIBLE COMPANY (LIMITED).—Mr. O. V. Morgan has retired from the Board of this Company.

NORTHERN ASSURANCE COMPANY.—The report for 1892 shows that in the fire department the net premiums amounted to £710,762, an increase of £21,464 over those of the previous year. The net losses were £480,100, and the total expenses of management, including commission, were £233,895, the year's operations, after making the usual provision for liability under current policies, resulting in a loss of £10,388. The total accumulated funds of the Company on December 31, 1892, amounted to £4,146,419.

PANULCILLO COPPER COMPANY (LIMITED).—At an extraordinary general meeting, held on Friday, it was resolved to voluntarily wind up the Company. Sir John Pender, G.C.M.G., M.P., who presided, said that the Directors would, before the holding of the confirmatory meeting, submit proposals for reconstructing the Company and developing the property.

OXFORD ELECTRIC COMPANY (LIMITED).—The Directors of this Company announce that Five per Cent. First Mortgage Debentures of £50 each, payable to bearer, being part of a total issue of £25,000, are offered for sale at par. Nearly the whole of the capital for this enterprise has been found by the Electric Construction Corporation (Limited), the debentures now offered being the first opportunity the public have had of obtaining an interest in the undertaking.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED.)—The receipts for the two weeks ended May 31st were £3,655, as compared with £3,215 for the corresponding period of last year.

Digitized by Google

STOCK EXCHANGE NOTICES.—Application has been made to the Stock Exchange Committee to appoint a special settling-day in, and to grant a quotation to, £50,000 Five per Cent. First Mortgage Debentures in Crompton and Co. (Limited).

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended June 2, 1893, after deducting 17 per cent. of the gross receipts, payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,438.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 787.—Vol. XXXI. FRIDAY, JUNE 16, 1893. PRICE FOURPENCE.
Annual Subscription (U.K.), 19/6

NOTES.

If the statements contained in M. Haubtmann's article, which will be found in another column, are correct, the decision recently given by the Court of Appeal in France in connection with the Faure accumulator patent is yet another instance of the vagaries of patent law, not in this country alone but all the world over. According to M. Haubtmann's reading of this remarkable decision, anyone who makes use, in no matter what way, of lead oxides or salts in the manufacture of accumulators is an infringer of the Faure patent. The brief history of the question prior to Faure's patent of 1880 given by M. Haubtmann is sufficient to show the tremendous extension of scope that has been given to this patent.

It is evident that the remedy for all the ills the patentee and manufacturer are heirs to does not consist merely in having expert assessors on the bench. In this action the experts and their report were very much in evidence, but the Court, nevertheless, gave judgment in a contrary sense. Hence these tears, and the demand of M. Haubtmann that a patent should be granted for an original and particular *process of manufacture* regardless of the existence of a patent for a general method. To take a concrete case. If A took out a patent for mechanically applying butter to bread, using preferably a spoon, M. Haubtmann's contention is that B should be given a patent for buttering bread with a knife. This would certainly mean death to master patents and to the patenting of embryonic ideas, which at present give so much employment, respectively, to lawyers and patent agents.

In printing the concluding portion of Mr. Nikola Tesla's lecture we must remind our readers that it is but a brief abstract of the original, as is indeed indicated by the numbering of the figures, seventeen of which we have had to omit. Those who are specially interested in the experiments, and in Mr. Tesla's speculations, should consult the full text of the lecture, which will be found complete in the *Electrical World* of New York of June 3rd.

Mr. Nikola Tesla has, we believe, a great respect for Prof. Dewar and his work, and it is, therefore, greatly to be regretted that he should, on the strength of mere newspaper accounts, suppose that Prof. Dewar has either suggested or has given the smallest support to the idea that a vacuum is opaque to radiant heat. Mr. Tesla describes an experiment with an incandescent button surrounded by two globes of glass; the outer globe remained cool so long as a vacuum was maintained between these globes, by a pump, but after sealing off, the outer globe became warmed. "From this I conjectured," says Mr. Tesla, "that if vacuous space (as Prof. Dewar finds) cannot convey heat, it is so merely in virtue of our rapid motion through space, or, generally speaking, by the motion of the medium relatively to us, for a permanent condition could not be maintained without the medium being constantly renewed. A vacuum cannot, according to all evidence, be permanently maintained around a hot body." This mare's-nest was started in *The Times*. As a specimen of daily newspaper science it was not more absurd than usual. The writer had evidently attended Prof. Dewar's lecture, and not content with reporting what he saw and heard, started the "opaque vacuum" theory. Prof. Dewar had no responsibility in the starting of this notion. So long as it remained a matter for newspaper discussion no harm was done, but if men of Mr. Nikola Tesla's standing are going to be misled by it, it is time that Prof. Dewar made a statement on the subject. We are not sure, however, that this would at once dispel the fallacy; it offers such a capital subject for writers of magazine articles.

The Perry meter has at last been put on the market. We gave a full account of an early form of this instrument in *The Electrician*, Vol. XXVII., p. 191. From that description it was evident that the meter gave promise of eclipsing all other kinds of continuous-current meters, in respect of true proportionality, temperature error, and range. How far Messrs. Johnson and Phillips, who have taken up the manufacture, have succeeded in retaining the theoretical features while the instrument has been reduced to a practical form, we are unable to say. We have received from them a calibration curve of a 60-ampere meter. The lowest reading on this curve is 2·5 amperes, and the "curve" is certainly a straight line from this point up to 60 amperes. We are informed that this meter starts at 0·09 ampere. The readings between this and 2·5 would be interesting. The limits of most meters are the starting current at one end of the range, and departure from proportionality, or over-heating at the other. Even meters of the Aron type, when provided with a synchronising arrangement, have a starting current. We presume that as the motion of the Perry meter is so slow, this being the important feature by which mechanical friction is minimised, its upper limit depends on heating.

The suggestion made by a correspondent for the improvement of the pupil system is hardly likely to commend itself to firms who receive pupils. He proposes that a workshop instructor should walk the shops, answer all questions, and give all needful instructions. To this omniscient individual the premium of one of the pupils is to be devoted, and this is put at £100 a year. A man who could answer one-half even of the reasonable questions, and could give one-half of the necessary instruction in all the shops, would be worth a good deal more than this to the firm. One of the greatest advantages of the pupil system is that the professor, the demonstrator, and the instructor, invaluable in their proper places, are absent. The pupil has to think for himself, not to be thought for, and to use his wits, not text-books. Judicious expenditure on drinks is indispensable; the pupil must learn this as part of his training for his future profession.

The general idea of our correspondent, Mr. W. S. Boult, in his letter which we publish elsewhere, is one which is quite in agreement with the experience of central-station engineers. The use of storage cells *does* assist the station to a more satisfactory day load, and brings about a better load factor; but their use must be properly undertaken, otherwise it becomes a case of penny wisdom and pound folly. Storage batteries plant requires more experience and skill in attendance than any other part of an electrical supply plant, and this can only be effectively given by grouping many cells into large sub-stations. To put cells into each consumer's house, or to have a large number of small capacity batteries, taking power at from 100 to 500 volts and supplying it to lamps, would be disastrous; disastrous as to capital outlay, as to the high rate of depreciation (much higher than 7½ per cent.), and the net efficiency of distribution, which would probably be almost worse than anything that has yet been published. Is our correspondent prepared to guarantee, or does he know of any electrical firm prepared to guarantee, small storage plant with unskilled attendance at 7½ per cent. of cost for repairs? The E.P.S. Company make a charge of from 10 to 20 per cent. for this purpose, under special conditions. And where shall we get such a small battery fixed in our house for £2 per lamp? By a curious coincidence, almost an identical suggestion is made by a correspondent of the *Gas World*, who proposes small gas-holders in private houses. Were, however, the available means of electric storage as perfect as in gas works, the whole business would be revolutionised, alternating currents would pass into ancient history, and the price of electric supply would fall considerably below that of gas.

A proposal which has been made to the Tiverton Town Council by Mr. Heathcoat-Amorey is one that we feel sure electric lighting contractors will approve of. The Town Council has been for some long time "thinking of going in for electric lighting," but financial considerations forbade anything more. Mr. Heathcoat-Amorey, however, public-spiritedly proposes that the inhabitants of Tiverton who really require the electric light should guarantee the Town Council against possible loss by agreeing to take electricity at 9d. a unit until the concern pays, the difference between 9d. and 6d., the normal working price, to be refunded to the guarantors as soon as the balance-sheet permits. The proposal is to be considered by the Electric Lighting Committee. If the suggested guarantee society ever gets to work on these terms, the inhabitants of Tiverton will have to be congratulated on having done something original and enterprising.

Whenever an electrical engineer happens to have had more than enough of the many phases of the alternate-current controversy, he cannot do better by way of antidote than betake himself to the serried columns of straightforward small type to be found in any journal devoted to the gas industry. There, at any rate, the typical higher harmonic and the double-distilled integral will cease from troubling. It was, therefore, with considerable alarm that a few days ago we came across an article in a gas contemporary, with the startling heading, "The Mathematics of Washers and Scrubbers." It was, however, a false alarm; as it is with the snakes in Iceland, so it is with washing and scrubbing mathematics: there are none. Makers of scrubbers and washers are, it appears, in an unregenerate state, and arrive at the proper dimensions of their interesting apparatus by guesswork "founded upon practical experience." Happy makers!

Bolton.—The special sub-committee of the Town Council have adopted the high-pressure alternating system, with four transformer sub stations.

Cable Interruptions: —

	Date of Interruptions.
Paramaribo-Cayenne	April 15th.
St. Thome-Loanda	May 30th.

Worcester.—A letter has been received from the Local Government Board sanctioning the loan applied for for the purpose of electric lighting.

Electricity in Japan.—We learn, says *Industries*, that the Japanese War Department has decided to adopt electric lighting at the various fortifications on the coast of Japan.

Royal Society.—The following Paper was down for reading yesterday at the Royal Society:—E. H. Barton: "Electrical Interference Phenomena, Somewhat Analogous to Newton's Rings."

Yarmouth.—The Local Government Board will hold an inquiry on Monday next into the electric light scheme of the Town Council, involving an outlay of some £15,000. The inspector will be Mr. F. H. Tulloch.

British Iron Trade Association.—We are requested to state that a Conference of the Iron and Steel Trades will be held at the Westminster Palace Hotel, on Thursday, June 29th, at 11 o'clock forenoon, when Papers will be read and discussed.

Institution of Electrical Engineers.—We are requested to state that as the hat and coat accommodation is very limited at the Galleries of the Royal Institute of Painters in Water Colours, it will be very desirable that gentlemen attending the President's *soirée* on the 23rd inst. should bring either crush or felt hats.

Obituary.—The death is announced of Mr. H. Hunton, of the electric telegraph department of the North-Eastern Railway, which occurred, after a short illness, on Wednesday last week. The deceased was for over 28 years with the North-Eastern Railway Company. Prior to his services under the Railway Company, he was with the British Magnetic Company.

The Telephone Dispute at Broughty Ferry.—At the meeting of the Broughty Ferry Police Commission on Monday last it was reported that the National Telephone Company had made an offer of £25 per annum for existing wayleaves, and 1s. yearly

Digitized by Google

at Whitsunday per pole on the streets, together with use of one instrument free and one at half rent. The Company's terms were accepted.

Errata.—Herr J. Fischer-Hinnen points out the following slips which occur in our abstract of his article on armature reactions, which appeared in *The Electrician* for May 26th, p. 104:—In Fig. 3 read "$2a$" instead of "a." In equation (3) read "L_3'" instead of "L'." Immediately above Fig. 7 read "a correspondingly strong *compensation* winding" instead of *magnet* winding."

Electro-Motors for Printing Presses.—We have received a copy of the *Galway Express* for June 10, 1893, which is the first newspaper printed by electric power in Ireland. The power is obtained from the 110-volt lighting circuit, and is supplied to that circuit from dynamos driven by water power. Electricity is sold in Galway at 5d. per unit for lighting and 3d. per unit for motive-power.

The Telephone Tubes in the City.—At the last meeting of the Commissioners of Sewers the Streets Committee presented a report with regard to the proposed use for telephonic purposes of certain of the tubes laid by the City of London Electric Lighting Company, and asked that further time should be given in order to consider the matter in connection with a communication from Mr. H. S. Foster, M.P. The recommendation was agreed to after some discussion.

The Azores Cable Contract.—The committees of the Departments of Public Works and Finance, appointed to consider the proposals of the Telegraph Construction and Maintenance and the Eastern Telegraph Companies for laying a cable from Lisbon to the Azores, with exclusive power to connect the Azores with England, Ireland, and other points in Europe, and with North America and Cuba, presented their report to the Cortes on 10th inst. Their decision was in favour of the proposals, and the Concession having been approved by the Chamber and House of Peers, was to be signed by the King yesterday.

Lightning Fatalities.—Two lives were lost by lightning in the townland of Barracliaring, parish of Donoughmore, on Friday evening last. Men were scattered all over the turf mountain, which extends for miles in the Donoughmore district, engaged in saving turbary, when about four o'clock a terrific hailstorm took place. When the hail ceased the thunder began, and two men were struck by lightning and instantly killed, while a third had a narrow escape. Near New Ross a girl was killed by lightning in a field, and a similar fate nearly overtook a man who was ploughing. He was severely injured by the lightning, while the two animals with which he was working were killed. On Sunday night at Swinford (County Mayo), a rainstorm set in, accompanied by thunder and lightning, and a farmer was killed.

The British Electric Light Company and the Newmarket Local Board.—The Board of Trade have issued a special report, with regard to the application made by the British Electric Light Company for a Provisional Order in respect of the district of the Newmarket Local Board. The Company were unable to produce the formal consent of the Local Board to the grant of the Order, and requested the Board of Trade to dispense with such consent. The report states that on the Local Board being informed that the Board of Trade proposed to dispense with their consent and grant an Order, the Local Board replied that, beyond objecting to the erection of overhead wires and to the opening of the streets during race weeks, they had no cause to show why their consent should not be dipensed with. The Board of Trade thereupon inserted a provision in the Order prohibiting the undertakers, except in cases of emergency, or with the consent of the Local Board, from breaking up or interfering with any street during the days fixed for race meetings.

Institution of Civil Engineers.—The following are some of the awards made for original communications submitted during the past session of this Institution:—For Papers read and discussed at the ordinary meetings, a Telford Medal and a Telford Premium were awarded to the late Mr. Willans (who had previously received a Watt Medal and a Telford Premium) for his Paper on "Steam-engine Trials"; and a George Stephenson Medal and a Telford Premium were awarded to Dr. Edward Hopkinson (who has previously received a Telford Medal and a Telford Premium) for his Paper on "Electrical Railways: the City and South London Railway." For a Paper printed in the *Proceedings* without being discussed, a Telford Premium was awarded to Mr. Charles Sheibner du Riche Preller for his account of the "Zurich Water-Supply, Power, and Electric Works." Mr. Preller has previously received Telford Premiums. For a Paper read at the supplemental meetings of students, a Miller Prize was awarded to Mr. Francis Gibson Baily for his Paper entitled "Some Points in the Regulation of Direct-Current Motors."

Fareham.—At the last meeting of the Local Board the members received a letter from the Fareham Gas Company asking that the Board would accept a tender from the Company for lighting for one or more years. The Lighting Committee reported that they were instructed by the Directors of the Fareham Electric Light Company that they would be pleased to renew the contract for light for three years on the same terms and conditions as specified in the existing contract, to supply current for 20 arc lamps and 92 incandescent lamps for £549 per annum, and one extra incandescent lamp on Wallington Bridge for £4. Mr. Drewitt said that the Lighting Committee were quite unanimous in their desire to see the town lighted with electricity for a further term of three years. He proposed that they should accept the tender of the Electric Light Company. Mr. Porter said he was of opinion that the town had been paying too large a sum for the electricity which had been supplied. He moved: "That tenders be invited for lighting the town and district of Fareham for one year, with electricity, gas, or oil, according to specifications to be drawn up by the surveyor." The motion of Mr. Porter, not being supported, was lost; and on Mr. Drewitt's proposition being put to the meeting it was carried.

The City Lighting.—At the meeting of the Common Council last week Mr. Altman said he desired to ask the Chairman of the Commissioners of Sewers whether any provision was made in the electric lighting contracts with reference to the supply of electricity to private consumers, a large number of whom some two years ago fitted their premises with the necessary appliances. Mr. Bridgman said: The three contracts entered into by the Commissioners of Sewers in relation to electric lighting related primarily to the public lighting of the streets in the City, but the clause in each of the contracts giving the wayleave for the private lighting mains provided that the contrators should supply electricity to any owner or occupier of property within a distance of 25 yards of the main within a reasonable time after the main was laid down. The remedy of owners or occupiers of property failing to obtain a supply of electricity was provided by the Provisional Order obtained by the contractors in respect of the district in which the property was situated. In addition to providing for the lighting of property on the main thoroughfares, each of the three Orders affecting the City required the undertakers, after the expiration of 18 months from the commencement of the Order, to lay down suitable and sufficient mains for the purposes of general supply upon being required to do so, in the manner provided by the Order.

Trunk Telephone Lines.—On Monday, in the House of Commons, Sir J. Fergusson asked the Postmaster-General what progress had been made under the Telegraph Act, 1892, in the acquisition of the trunk lines of telephones from the companies, in the construction of additional lines, and in the delimitation of the exchange areas. Mr. A. Morley replied that there had been some delay in carrying out the arrangements which were the subject of discussion before the late Government left office, due partly to the death of the late Duke of Marlborough, who was one of those who conducted the negotiations on behalf of the telephone companies. Considerable progress had, however, now been made, and the delimitation of the exchange areas had been practically completed. He trusted that the transfer of the trunk lines of the companies to the Post Office would not be long delayed. The construction of seven additional lines by the Post Office, including a submarine telephone cable to Ireland, had been completed, and progress has been made with the construction of main lines from London to twelve towns in the north, including Glasgow and Edinburgh, and from South

Digitized by Google

Wales and the south-west of England to the coal ports on the north-east coast. These works were of considerable magnitude, and he did not anticipate that they would be completed before the end of the financial year.

Arago.—On Sunday last was unveiled a statue of Arago, erected in front of the Paris Observatory. Arago, who was born in 1786, and died in 1853, was elected a member of the Académie des Sciences when only 23. To Arago is due the discovery of the electro-magnetic phenomenon (once known as "Arago's rotations") of a metal disc rotated under a magnetic needle dragging the latter round with it, and a magnet revolved under a disc dragging the disc round with it. In September, 1820, Arago discovered that a wire traversed by an electric current attracted iron filings, and that he could permanently magnetise a steel needle by placing it at right angles to a wire traversed by an electric current. He greatly promoted the general acceptance of the undulatory theory of light, and established the connection between the appearances of the *aurora borealis* and terrestrial magnetic disturbances. Arago was an indefatigable propagator of scientific ideas. It was at his suggestion that a chair of popular astronomy was founded at the Paris Observatory, and in 1812 he commenced a series of popular astronomical lectures that attracted all Paris. In 1816 he and Gay Lussac founded the *Annales de Chimie et de Physique*, and later on he started the *Comptes Rendus*. In 1830 he became head of the Observatory and Perpetual Secretary of the Académie des Sciences. He subsequently became mixed up in the stormy politics of the day.

Three-Ton Electric Crane.—An electric crane is now at work on the Southampton Town Quay unloading vessels of the Clyde Shipping Company. A second crane will be erected very shortly. For lifting, a "Statter" motor, taking 200 volts and 225 amperes, at 600 revolutions per minute, is used. This motor runs continuously, and drives through worm and worm-wheel, the former running in an oil bath. In regular work, lifting 10 to 20 cwt. loads, the average current taken by this motor is about 50 amperes. To lift and lower, the worm wheel is put in and out of gear with the barrel by means of a "Lindsey" transmitter, worked by a lever placed on the driving platform. A powerful band brake is provided, and operated by a foot lever; and, in addition, there is a magnetic brake, which acts and holds the load in case the supply of current to the crane should cease at the moment that the load is being lifted. The average current required to slew is from 15 to 20 amperes. The current for driving the cranes is supplied by the Southampton Electric Light Company, and is fed through special mains laid along the Quay to a pair of overhead conductors of silicium bronze wire. The cranes have been constructed to the specification of Mr. J. G. W. Aldridge, the electrical engineer to the Harbour Commissioners, by Messrs. Statter and Co., working in conjunction with Messrs. Stothert and Pitt, to whom was entrusted the building of the gantries and the crane gearing.

Central London Railway.—Colonel Haywood has just made a report upon the application and plans of the Central London Railway Company for the construction of a station fronting the Mansion House. The plans show altogether seven staircases in connection with the subways and the railway station. The principal access to the subways and station will be by two staircases on the western front of the Royal Exchange, and another at the junction of Queen Victoria-street with the Poultry. The two Exchange staircases will be always open; all the others are to be so constructed as to be easily closed up. It is intended that there shall be a double staircase—one for the up and the other for the down traffic—in front of the London, Liverpool, and Globe Insurance office. Two staircases of a similar character will be made at the junction of Princes-street with Mansion House-street. Another staircase for a similar purpose will be formed in Mansion House-place, and will occupy the whole of the present footway at the spot, and the existing footway next to the Mansion House will, therefore, be permanently removed. Colonel Haywood states that he has been informed by the engineer to the railway that the Bank of England would not permit any part of their building to be interfered with, and the Company has not sought power to take the land for the purpose. The subways will be lighted by electricity. By Clause 68 of the Act of 1891 there are to be no advertisments on any part of the Company's premises in view of the public, while under Clause 69 the Company must deposit objects of geological or antiquarian interest at the Guildhall, to become the property of the Corporation.

The Telephones and Electric Traction.—The Joint Committee of the Houses of Lords and Commons appointed to inquire into the question of uniform protective clauses for telephone and other companies, in relation to Bills promoted for electric railways and tramways, met on Monday to select a Chairman and to consider the course of procedure. Lord Cross having been chosen Chairman of the Committee, Sir Theodore Martin, on behalf of the National Telephone Company, asked that they might be represented by counsel, the adoption of which course, he believed, would much abridge the length of the inquiry. Similar applications were made on behalf of the Associated Railway Companies, the Electric Traction interest, the Association of Municipal Corporations, the London County Council, and Scottish Corporations. The Committee room was then cleared, and on the re-admission of the public, Lord Cross said that the Committee had decided to meet again on Monday next at 2 o'clock, for the purpose of hearing Sir Courtenay Boyle on behalf of the Board of Trade. He, of course, would not be cross-examined by Counsel at all. The Committee would afterwards meet *de die in diem* at 11 o'clock, with the exception of Saturdays. They had decided to hear one counsel only from the following bodies:—The Railways Association, the National Telephone Company, the Electric Tramways and Railways together, the Electric Lighting Companies, and one representing all Municipalities, both English and Scottish, including the London County Council. The Committee would only hear one counsel speak on behalf of each of the five bodies named. Sir Theodore Martin applied that the Committee would take the case of the National Telephone Company immediately after the conclusion of Sir Courtenay Boyle's evidence, and the Committee acceded to this course. The Committee then adjourned.

Electric Lighting at Kensington.—At the meeting of the Kensington Vestry last week the Select Electric Lighting Company appointed by the Vestry on December 7th last, submitted the following report:—"The Committee have considered a letter received from the Notting-hill Electric Lighting Company, intimating that they are prepared to take over the area in North Kensington which the House-to-House Company proposes to abandon, and submitting a schedule of the streets which they agree should be made compulsory, but before further considering this application on the part of the Company, the Committee have deemed it desirable to request them to furnish a plan showing the streets in their present area in which they have already laid electric mains, and also to supply further information as to the actual financial position of the Company. That the Committee had before them, pursuant to the reference by the Vestry of May 24th last, the letter from Sir Frederick Leighton, Bart., P.R.A., calling attention to the fact that electric lighting mains have not been laid in Holland-park-road by the Notting-hill Electric Supply Company, and inquiring whether the Vestry can enforce the supply of electrical energy to his house (No. 2 in the road), or whether steps might be taken to rescind the Company's order, and have requested the Vestry Clerk to forward the Company a copy of the complaint referred to, accompanied with a request that the Committee may be furnished by the Company with an explanation of their default in the matter. That the Committee have further considered the reference by the Vestry of March 1st last, as to whether it would be advisable for the Vestry to apply for a Provisional Order empowering them to lay down plant for lighting the streets of the parish with electricity, and also to supply electricity to any part of the parish in which mains have not already been laid down by existing electric lighting companies, and have again had before them the report which has been prepared by the lighting engineer on the subject; and recommending that the lighting engineer be empowered to place himself in communication with a consulting electrical engineer, to be selected by your Committee, to report jointly with him upon the whole question." The report was agreed to.

THE "HARP" ARC LAMP.

An arc lamp of remarkable simplicity has been brought out by Messrs. Chester and Rathbone. The pattern, which is illustrated in Fig. 1, is intended for simple parallel working for continuous or for alternating currents. The carbon holders slide freely on a brass tube, and are prevented from revolving round it by a lightly strained wire guide. The holders are connected by a flexible braided wire cord which passes over a rubber wheel. This wheel, as will be seen in Fig. 2, is mounted on a hanging frame, across the top of which is fixed an armature and tension lever. A club-foot electro-magnet, that is, a horse-shoe with one coil only, and having a laminated core, pulls down the armature when the current is turned on. A rubber band on the armature softens the blow. The rubber wheel swings to one side, and in consequence of the arrangement of the cords, strikes the arc. The wheel is then held firmly against a brass stop, but as the current diminishes, the pressure is relaxed until the greater weight of the upper carbon holder causes it to feed, the rubber wheel assuming the position shown by the dotted circle.

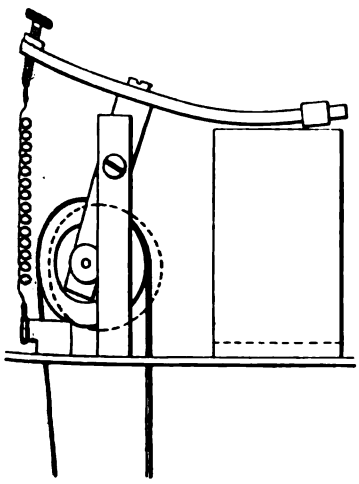

FIG. 2.

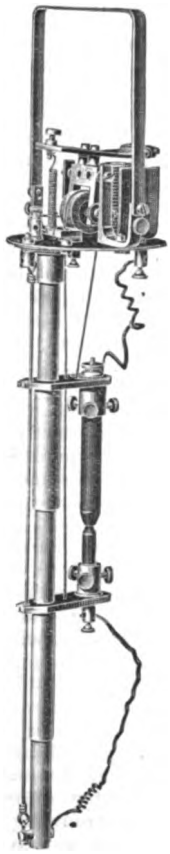

FIG. 1.—The "Harp" Lamp.

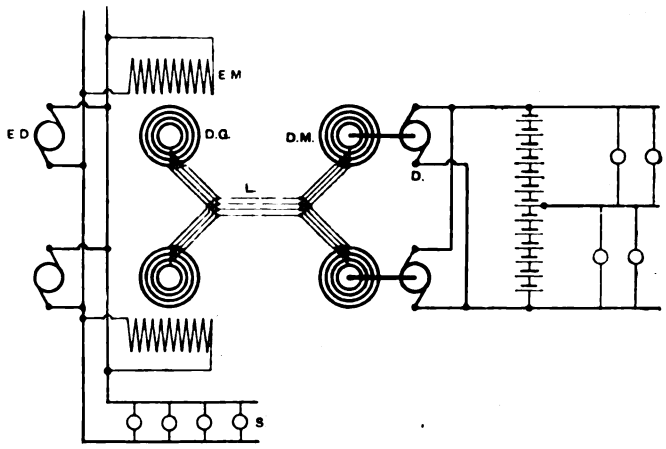
Should the lamp over-feed, the device allows a little recovery. By a slight adjustment of the control spring the lamp may be used for alternating currents. The use of a flexible wire cord has been proved by experience to be satisfactory, and avoids the necessity for absolute straightness of the carbon rod where a clutch is used, and for the wheel work which is required when racks are employed. The "Harp" lamp admits of the addition of a shunt coil in the place of the tension spring where lamps are to be run in series, and we are informed that Messrs. Chester and Rathbone have such lamps in hand. In addition to the extreme simplicity of this invention, it should be observed that the absence of a carbon rod allows this lamp to be used in situations in which there is but little head room; a very important consideration, which has often prevented the use of arc lamps in factories. We are informed that the rubber wheels show no sign of deterioration after some months' work, but even if this should occur, a metal wheel could easily be substituted for the rubber one, and a spring abutment for the fixed metal block.

ELECTRIC LIGHTING IN BUDAPEST.

The Austrian Gas Company is about to undertake the electric lighting of Budapest, and the way in which the scheme is proposed to be carried out is of some technical interest.

The electric light works are to be about two miles outside the town, and it is proposed to carry out the transmission by means of two-phase currents. The station plant will at first be laid down with a view of supplying 20,000 8 c.p. lamps, the distribution net-work being equal to a load of 32,000 lamps.



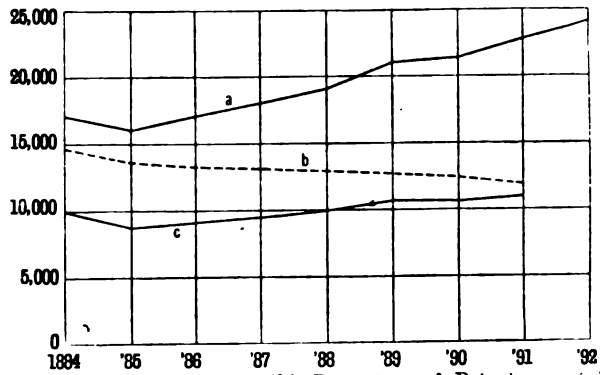
S. Lighting at Station E.D. Exciting Dynamo. E.M. Exciting Magnets. D.G. Alternate Double-Current Generator. D.M. Alternate Double-Current Motor. D. Continuous-Current Dynamo. L. Line.

The station plant is to consist of two vertical, triple-expansion 500 H.P. machines, coupled direct to 1,800 volt, 100-ampere, two-phase dynamos, which will be worked in parallel. The line will consist of two armoured lead-covered concentric cables, the fourth conductor acting as a reserve. The two-phase current will be taken to a sub-station, where it will drive motors coupled direct to dynamos, supplying current to the lamps and charging a battery of accumulators of a capacity of about 1,500 to 2,200 ampere-hours, and capable of discharging at the rate of 1,000 amperes.

This installation, which is shown diagrammatically in the annexed sketch, is to be carried out by Messrs. Schuckert and Co., of Nuremburg, who are under contract to have a portion of the installation in working order by the coming winter.

PATENTS IN 1892.

During last year 24,171 patents were applied for, as against 22,888 in 1891. It will be observed from the annexed curves



(a.) Applications for Patents. (b.) Percentage of Patents granted to number of applications. (c.) Patents granted.

that ever since 1885 there has been a steady increase in the number of patents applied for, and an equally steady decrease in the *percentage* actually granted. This, the Comptroller-General remarks in his report, "is doubtless in some measure owing to the advantage taken by inventors of the provisions of Section 4 of the Amendment Act of 1885, which prescribed that abandoned applications should at no time be open to

Digitized by Google

public inspection or be published by the Comptroller. Consequently inventors who may be unable to proceed with their applications within the term first allowed by law, are now in a position to renew their applications from time to time, without risk of losing their rights, which would have taken place under the law as it stood before the Amendment above mentioned." However, notwithstanding the diminished *proportion* of applications which obtain patents, the total number of patents issued annually has, it will be seen, considerably increased since 1885.

The gross income of the Patent Office is now close on £200,000, of which over £180,000 accrues from patent fees. The gross expenditure last year was £96,822, of which salaries accounted for £52,835, printing for £19,000, and new buildings for £13,005; the surplus being £103,036. If we deduct the sums devoted to buildings it will be found that while the gross receipts of the Patent Office have increased some 106 per cent. since 1885, the gross expenditure has increased less than 8 per cent.

THE FAURE-SELLON-VOLCKMAR PATENTS IN THE FRENCH COURTS.*

BY CH. HAUBTMANN.

The judgment given on the 5th May by the Court of Appeal in Paris in the action brought by the Société Française des Accumulateurs, has produced a justifiable sensation in electrical circles and in the law courts. Indeed, the judgment in favour of the Société Française, declaring all who employ lead salts or oxides in the manufacture of accumulators infringers of the Faure patent, is big with consequences by reason of the judges having given their decision in the face of the contrary report of the experts and the opinion of the Ministère Public.

Looking at this fact by itself, the question immediately arises, why nominate experts to advise in an action for infringement if no notice be taken of their report in the judgment? When it is a question of infringement there are only two possible ways of looking at things, either the patents said to be infringed are valid, or they are not. Now to decide this very often exceedingly delicate question, a thorough knowledge of the question at issue is requisite, and it is especially necessary to examine with great care the invalidating instances which defendants never fail to produce. In many cases the scientific and commercial knowledge of the experts are put to a severe test, and the drawing up of a report is not always an easy matter even to experienced men. So we were a little surprised to see the Court pass over the advice of the competent men whose assistance it had invoked, and settle the matter in a purely judicial sense, letting alone the commercial and scientific aspect of the question. If this mode of procedure takes root amongst us we must anticipate disagreeable surprises for French manufacturers, for if it be granted that the advice of the experts is only of secondary importance in commercial cases, one may well ask whether the decisions given will not, as a rule, bear the impress of absurdity.

In the Faure accumulator action the experts had to answer two questions:—(i.) Examine the Faure-Sellon-Volckmar patents, and say if they are valid, and for what purpose. (ii.) Examine the alleged infringing apparatus, and point out the differences and the resemblances that exist between it and the patented apparatus, and declare whether the alleged infringements are really such.

The first question must have put the experts in a terrible hole. In fact, nothing can well be more difficult than to determine the validity or invalidity of a patent which has for its object a process of manufacture on which more or less public experiments are constantly being made. A newspaper article or an author ventilates an idea, which is never put into practice, yet it may prove an anticipation. Similarly, more or less successful laboratory experiments, if sufficiently notorious, may prove an obstacle to the validity of a patent taken out by anyone ignorant of these experiments. And, as far as accumulators are concerned, the number of articles that have been written and the number of experiments that have been made are truly incredible.

I have no intention of going over the Faure patent action again. I only desire to point out the difficult situation which will be created for manufacturers if the Courts set to work to sanction monopolies based on patents that experts and experienced men consider invalid.

So far as the use of lead salts and oxides in the manufacture of accumulators is concerned, the anticipations urged by the defendants, owners of the Philippart process, deserve to be examined with much care, and after ripe reflection one still asks oneself who is the first and true inventor of these accumulators. I, of course, thoroughly recognise the value of the work done and services rendered by Faure in this matter of electric accumulators, and it is true that the results of his labours set forth in his patent of 1881 should enjoy an assured commercial protection. But it is a long cry from that to the granting of a monopoly of all lead salts and oxides. Methods of manufacture go for something in estimating the commercial value of accumulators. Moreover, because a principle has been more or less vaguely pointed out in a patent or pamphlet, it certainly does not do to jump to the conclusion that it is the absolute property of the person who first mentioned it. If this were to be the case manufacturing would be impossible, as this would be the greatest obstacle one could oppose to its progress. To convince oneself of this, it is only necessary to run over the tests of the patents taken out during the last fifty years, and one immediately realises the formidable number of patents taken out for the most part by ignoramuses who, infatuated with an idea, patent it at any cost and never succeed in putting it into a practical shape. Sometimes the idea is a good one, and when it is hit upon later on by an experienced practical man it gives excellent results. Nine times out of ten the commercial engineer has not the time necessary to look up previous work, and is generally ignorant of previous failures. Arrived at his goal with his patent made public, patent agents trot out from goodness knows where eight, ten, or twenty patents on the same thing, which often have much resemblance, fundamentally, to the invention in question. In such instances success lies, as a rule, in details, in factory methods, and if twenty men have previously failed it is because they did not know how to set to work. From the point of view of equity the *process of manufacture* belongs rightly to him who has discovered it, and the principle enunciated, even clearly in previous patents, ought not to affect those who have found a way of putting it into practice. Of course, the law does not allow principles to be patented, but it is often an easy matter to get round the law and to patent a principle; witness this very patent of Faure's.

In Faure's patent of October 20, 1880, and in the two additions of January 10, 1881, and October 19, 1881, he claims the use of two electrodes coated with metallic salts, particularly oxide of lead. Now Poggendorff tried two electrodes consisting of platinum strip covered with platinum oxide. In 1856 de la Rive tried a secondary cell with a strip of platinum covered with lead peroxide and a plain strip of platinum. In 1854, Sinsteden made a secondary cell with two lead electrodes, and he noticed that one of these electrodes became covered with lead peroxide and the other with hydrogen. In 1861, Kirchoff made a cell consisting of two strips of perforated platinum. On one he placed lead peroxide, on the other lead crystals. He also tried two lead strips. In 1860, Planté invented his accumulators with two lead strips. He showed that lead was the best metal to use, and that it was necessary that one of the strips should be covered with lead peroxide and the other with spongy lead. Again, we find, in an article in *The Electrician* of 1863, the description of a secondary cell consisting of a strip of platinum surrounded with lead peroxide, put on mechanically, and of a sheet of zinc. In 1870, Planté tried to mechanically apply red lead (minium) and protoxide of lead (litharge) to lead electrodes. In 1879-80 Brush made the same attempts as Planté, so far as concerns the application of lead oxides to lead electrodes. There is, consequently, no room for doubt on this point. Two similar electrodes had been employed long before Faure and lead oxide had been tried in secondary cells, long before Faure's patent of 1880. The only thing original in this patent is the method of fixing and retaining the oxide on the electrodes. That idea, abandoned to-day, gave birth to the patent of Volckmar of October, 1881, in which was claimed the use of cellules in which the active material is lodged, in fact, the grid plate of the modern accumulator. I mentioned above several examples of perforated secondary cell electrodes. Finally on March 10, 1882, Sellon patented the lead antimony alloy for accumulator grids. The Sellon patent was invalidated by a decree of the United States Courts, which runs as follows:—No one may claim that a piece of apparatus made in part or in whole of a substance more suitable for the purpose which the piece of apparatus is intended for than the substance of which the original piece of apparatus is made can be distinguished from the original because it is better and, for this reason, cheaper, and that it gives on that account a right to a patent in the sense used in the patent law.

To sum up, the principle, or rather the use of lead oxides in the manufacture of secondary cells, was not, as I have shown above, employed for the first time by Faure, but it is just to recognise that with the Faure patent, the validity of which we do not wish to discuss, the Volckmar grid, and the Sellon alloy, commercial accumulators, unknown until then, were made in 1881-82.

According to my way of looking at things, the commercial value of these accumulators rests entirely on the way they are made, and that it is owing to workshop details that the manufacturers succeeded where others failed. It is, therefore, just that those who have obtained these results should be safeguarded to a certain

* From *L'Electricien*.

Digitized by Google

extent. In these days, electric lighting developing in an extraordinary manner, accumulators became, in many central stations, a means of distribution, and every endeavour was made to improve them, both from the point of view of manufacture and of efficiency. It was then that the Faure patent became an obstacle, for its owners immediately claimed to be the only ones who could use lead salts or oxides. Is this claim valid? Evidently not, since long before Faure, lead oxide, applied mechanically to the electrodes, was used in secondary cells. The French Courts have held otherwise, and I have no qualification to criticise this decision, which converts the manufacture of accumulators into a monopoly, and renders liable to infringement suits all who are employed in the business, even if they go to work in a very different way to Faure. To day it is certain that, owing to this decision, the mere fact of using a lead salt in making an accumulator amounts to an infringement of the Faure patent. I admit I never should have thought so, and many others are in like case.

THE ALTERNATE-CURRENT MOTOR CONTROVERSY.

In our issue of May 19th we noticed an attack on Mr. Brown's motor, to which Mr. Brown replies in the *Elektrotechnische Zeitschrift* for the same date. He remarks that the "3-4 H.P." motor shown him in June, 1890, was about as big as a 10-15 H.P. motor of present design, and he considers that it requires some assurance to allude to this motor as if it only wanted little to make it a really practical machine, as it had practically no efficiency and made a terrible noise. Mr. Brown said he recommended his people to take out a licence because he thought he could correct the error of its ways, and because at that time he thought Herr Dobrowolsky was the inventor of the three-phase system; he never laid claim to the invention of the three-phase motor, but he claims to have been the first to make a practical one. Herr Dobrowolsky came to Oerlikon to see how it was done, and it was this Brown motor that decided the character of the Lauffen-Heilbronn transmission. As regards the armature, Mr. Brown considers that the Dobrowolsky patent shows an armature in which eddy currents are encourged, whereas in his own armature they are got rid of, and only induced currents in the winding are used. As regards a quotation from Mr. Swinburne, Mr. Brown says that his motors have been working for some time on circuits of a frequency of 100 and 140 ∿. He concludes by promising shortly to publish more figures for single-phase motors of different sizes, and made for a periodicity of 40-60.

To this Herr Dobrowolsky replies that since Mr. Brown has not published data as challenged, he considers himself justified in believing in the inferiority of the Brown motor; that the efficiency of the 3-4 H.P. motor was not 0, as its output could be raised to 6 H.P.; the difficulty was in starting, as the initial torque was small. The question of the armature he cannot discuss, as the Allgemeine Elektricitäts Gesellschaft has informed Mr. Brown that they consider that he infringes their patent.

Mr. Brown finally retorts that, of course, he will not publish data too soon. He regrets that Herr Dobrowolsky in 1890 did not call his attention to the fact that his motor had an ou put, and recommends any person interested to look up the old papers of Dobrowolsky and Swinburne and see how much information he finds on the subject of the design of alternate-current motors.

Our own contribution to this apparently interminable discussion is the following letter received from Herr Arnold, of the Oerlikon Works:—"In your valuable paper the so-called Brown alternate-current motor, which is a close copy of the Oerlikon alternate-current motor that was at work in 1892, was recently appreciatively noticed. I have taken the liberty of sending you by newspaper post a copy of the *Elektrotechnische Zeitschrift*, containing an article of mine, and I should be glad if you would take notice of it, observing that the Oerlikon Works claim priority for these motors."

The article referred to is to the following effect:—"Elihu Thomson and Nikola Tesla laid the foundations of the system of design of alternate current motors long ago, although practical difficulties retarded their development, and experiments with polyphase motors have only recently cleared the pound for the design of a single-phase moter, several of which are now in daily use. Elihu Thomson was the first to show that a conductor placed in an alternating field could be made to rotate if started, or if placed unsymmetrically in that field, and tended to produce a torque, an effect which is much increased by making the conductor the short circuited winding of a laminated iron armature. Such motors have no collectors or brushes, and rotate in the direction of the necessary starting impulse; and Tesla's patent, No. 401,520, February, 1889, is very important in this connection. By this method the exciting coils are divided into two parts, the self-induction of which differs, and at starting, these circuits are placed in parallel. The currents in them differing in phase, a rotating field is produced, which starts the motor. One winding is then either cut out or placed in series with the other. But Tesla's method of armature construction, and his magnetic design, precluded success. For successful motors, the magnetic resistance should be small, and deep and wide recesses in field armatures must be avoided. The best arrangement is that in which the wires are in holes or in narrow slots, as in the Wenström design, adopted by Mr. Brown. These considerations apply, not only to polyphase, but to single-phase motors, for every polyphase motor can be made into one for ordinary alternate currents. The motors of the Oerlikon factory are examples of this, both polyphase and single-phase motors being of the following construction:—The 'inducing' coils surrounding the armature are wound as Gramme ring windings, and the wires are placed in recesses in the iron. The armature has copper rods passing through holes in the plates, and either coupled at each end to copper rings, short-circuiting them, or in groups. These motors are now made up to 12 H.P., but one of 250 H.P. has been running in connection with the Hochfelden-Oerlikon transmission for several months. An idea of the dimensions may be gathered from the following figures relating to a 6-H.P. motor:—Speed, 1,200; watts taken, 5,800; efficiency, 76 per cent.; length, 2ft.; width, 2ft. 9in.; height, 2ft. 3in.; weight, 6·4 cwt. Several methods of starting are used. Tesla's has the disadvantage of taking a very large current, but in small motors it can be applied, and the starting helped by a judicious push. A neat method is to connect the Gramme winding of the field to a collector (like a direct-current armature) fixed in any convenient place and supplied with rotating brushes; if these be rotated when the current is switched on, a rotatory field is produced which starts the motor, and the brushes can then be left in any position. Another way is that used by Mr. Brown and for which the Oerlikon Company filed a provisional patent last year. A description of the Oerlikon motors follows, which work with a periodicity of 40-70 ∿, and in which the Tesla method of starting is used. They contain all the important novelties and properties as described by Mr. Brown, and were first described in the *Neue Bündner Zeitung* of December 25, 1892, and two months before the appearance of his article."

CONDENSING PLANT FOR THE BRISTOL CENTRAL STATION.

Messrs. W. H. Allen and Co., of Lambeth, who have the whole of the contract for the condensing plant for the long incubating Bristol electric-light station, are now about to fix this portion of the plant into place. The proximity of this station to the Avon renders condensing practicable—the site having been selected, in fact, with this in view—while the extreme dirtiness of the river water, and the strong chemicals dissolved in it, make it necessary to have a special form of condenser. This is the first occasion on which a large condensing plant of this kind has been adopted for central stations; and Messrs. Allen and Co. are to be congratulated on the manner in which, in the equipment of this plant, they have surmounted the many special difficulties which have been encountered.

The entire plant is sub-divided into three similar sections, consisting each of a surface condenser, an evaporator, and air and circulating pumps, with engines for driving them. Each section is capable of condensing 30,000lb. of exhaust steam per hour, and consists of a horizontal circular shell, 4ft. 1in. in diameter and 8ft. 6in. between tube plates, with internal tube plates, to which a large number of longitudinal ¾in. gun-metal tubes, of No. 18 S.W.G., with a total condensing surface of 2,422 square feet, are fastened by ferules. By means of a diaphragm at the front end of the condenser shell the tubes are divided into two sets, one for forward and one for return flow, by which the cold water is carried twice along the condenser. The circulating water occupies the spaces between the tube plates and the ends of the shell, and completely surrounding the tubes. Circulation is produced by the "Conqueror" centrifugal pumps, direct-coupled to Messrs. Allen and Co.'s vertical compound engines. The engine cylinders are 6in. and 12in. diameter, and 12in. stroke, and the pumps are capable of raising from 2,500 to 2,800 gallons of water per minute from the river, which is at a depth of 15ft. below the level of the engines. A safety governor is fitted to each of these engines, which would come into action in the event of the pump losing its water, and each pump is provided with a charging apparatus, by which it may be quickly charged. Surmounting each of the condenser shells there is a supplementary feed evaporator, by means of which, in the event of the water in the hot well failing, an additional supply of hot clean water can be given to the hot well. This evaporator is of novel construction, and consists of two cylindrical shells, arranged like the shell and flue of a Cornish boiler, with the inner shell crossed by 26 diagonal water tubes of 2in. diameter. The exhaust steam passes through the inner shell and around the cross tubes on its way to the condenser, and gives up some of its heat to a large bulk of clean water which fills the spaces between the outer

Digitized by Google

and inner shells. The vapour which is thereby produced passes down to the condenser, and mixes with the exhaust steam. Both are then removed to the hot well by means of the air-pump. In the event of the exhaust steam not evaporating a sufficient quantity of water, the evaporator may be supplied with a circulation of live steam, which can be admitted from the boilers through a ¾in. pipe. The vapour is taken from the evaporator by means of a 3in. pipe.

The air pumps are of large capacity, and are specially designed for long and continuous working. Each pump has a capacity of 250 cubic ft. per minute, and is direct driven by one of Messrs. Allen and Co.'s compound engines. The engine cylinders are of 10in. and 16in. diameter, and the pump barrels are of 16in. diameter; the stroke is 10in., the piston rods of the engines being rigidly coupled at the crosshead to the pump rods by means of two stiff rods working in guides. The crosshead also drives a crank shaft, by means of a connecting rod; but the thrusts on the cranks are very small, as they are only required to supply motion to two fly-wheels which are keyed to the shaft. The fly-wheels are designed to give steady rotation at low speeds; and a crank shaft governor, actuating the piston expansion valves, controls the engines when the pumps fail to lift water. Special arrangements have been made for lubricating these engines from one common oil reservoir, the oil being distributed through pipes to each of the working parts, and the feed being regulated by sight.

The exhaust steam from all the engines passes directly to a cast-iron ring pipe, from which it is passed into the three condensers. The pipes are of 12in. and 15in. diameter, and have four large copper expansion joints; and the main exhaust to the condenser is 18in. in diameter. The pipes are anchored at two ends, having the sides free to expand. The whole of the exhaust can be turned into the atmosphere in the event of a breakdown of any portion of the condensing plant. The main steam ring, which is also supplied by these engineers, consists of pipes 6in. and 7in. in diameter, with connections from the boilers of 5in. in diameter. All the flanges and T-joints are electrically welded by the Bernardos process. These electrically welded pipes have, so far as we are aware, been put into no large station, except that of the Metropolitan Company at Amberley-road, Paddington; and it is, without doubt, considerably in advance of the usual practice, as the steam pipes have been successfully subjected to a pressure of 1,500lb. per sq. in.

THE ELECTROLYSIS OF WATER PIPES.*

BY C. H. MORSE.

When electric cars were first put in operation in Cambridge (Mass.) they depended upon mother earth, the water pipes, the gas pipes, and anything over which the current could flow, to convey it to the station or act as a sewer. No thought was given to the loss which would result to the Company from doing this, to say nothing about the effect upon pipes. I can, perhaps, illustrate this loss by saying that three months ago, in parts of Cambridge, the loss of pressure due to the power which was required to force this current back over this uncertain path was 20 per cent.

When the Railroad Company put in their power plant, they run large numbers of feeders and one wire between the rails, and attached the two rails to this return wire. This became very soon an uncertain path, as it was found that electrolytic action took place upon this wire and it disappeared in places. They thought at first that it was due to something in the soil, but it was very soon traced to the enemy, that is, electrolytic action. I remember the practical experience we had with these dead rails, as we call them. When this wire was eaten off and a car came on to that section, if by any chance you placed one foot upon the rail and another upon the ground near it, shocks could be obtained.

Mr. Nevons and I went to the different places where we had traced these difficulties, or where they had been called to our attention rather, and found that lead pipes had disappeared in a short space of time, some even in six or eight weeks. Iron pipes had been tried with the same result, also galvanised iron; brass pipe had been put in, and deterioration was noticed at once. Rustless iron was tried, and it did rust decidedly. It was not the work of any mysterious agent, but was the result of what almost all of you have seen in school experiments, that is, the decomposition of water. A speedy remedy for that, of course, was easily apparent, that was to reverse the current. So the officials of the West End Railroad Company were invited to a Conference with the Water Board and myself, and I am pleased to say the Company were willing and anxious to do anything in their power to obviate this difficulty. A certain amount of credit belongs to them for that, although, of course, they had themselves a reason for wanting to do it. They were losing anywhere from 5 to 20 per cent. of their power in this return.

Observations were made by several of the waterworks *employés* unintentionally. Such an immense amount of current was flowing over the pipes that upon attempting to make a joint by putting oakum around the pipe, it was found that the electric arc was sufficient to set fire to the oakum, frightening the men considerably. Tests were made in different parts of the city by means of instruments adapted for the purpose, and we found between North Cambridge, Harvard Square, Central Square, and East Cambridge a fall of potential all the way from 25 to 45 volts. Now, there should be no fall of potential, but there was a loss of from 25 to 45 volts, from 500 volts, which is the maximum pressure, making more loss than can be allowed with economy. When we attached to the negative pole of the machine and made our tests from Harvard Square, we found a loss of 100 volts, or 20 per cent. of the pressure. You can now see, as I said before, why the Company was very ready to take hold of this matter.

How are we to remedy the difficulty? I know of no way by which we can use the single trolley wire system and overcome this difficulty without putting up an immense amount of overhead returns, through which the resistance will be reduced to almost nothing. How far the Company will be willing to go in this I cannot say. Their spirit has been so admirable in the past I have no right to suppose but what they are willing to carry it to that extent. Certainly, the city will require it carried to such an extent that the pipes will be in perfect safety. The maximum amount of current which can be allowed to go over them I am unable to tell you at present, but a series of experiments are being conducted now at my house to determine this. I have some pipes buried in the earth, the current flowing over them, and I am watching carefully the deterioration daily. I am in hopes to make a report soon to the Water Board upon the maximum amount which can be allowed to flow upon iron pipes.

By doing what we did, reversing the current and attaching our water pipes to the negative pole of the dynamo, we hurt one of our old friends seriously, that is, the Gas Company. You see the effect. The current will flow on the water pipes, and it has an easy chance to leave them through their connection with the negative pole of the dynamo. Now it flows along on a gas pipe, and as soon as it can it will leave the gas pipe to take to the water pipe. I felt it my duty to make this clear to the President of the Gas Company, and called his attention to it, saying that something ought to be done to protect him, and a Conference was had between the railroad people and the Gas Company, and I was invited to be present. At that time we made an arrangement with the Company which will help it somewhat in that direction, and help us as well as them. We propose now to connect the gas pipes and the water pipes together in all parts of the city. It will be done in buildings. A man from the West End Company has been appointed who goes as a gas man to the different stores and factories, and in those places he will solder a wire to the gas pipe and also to the water pipe. This can do no injury to either, but will decidedly help both companies.

I was somewhat surprised at the way they attempted at first to return the current. There are girder rails that have, we will say, 10 sq. in., some of them have as high as 14 sq. in. sectional area. That would have a carrying capacity equal to a piece of copper 2in. square. And yet these rails are bonded by a No. 4 copper wire, a wire smaller than a lead pencil. It seems quite ridiculous that they should require this little bit of fine copper wire to carry as much current as a big rail, where they should have a piece of copper wire, as I said before, for these big rails, of at least 2 sq. in. sectional area. There is another remedy also which we hope to carry out early in the spring, and that is to abolish completely this return wire between the rails, by cutting it into sections of about 400ft., and connect each of these sections with the return wires. Most of the current will then return by these copper wires. Of course, some of it will flow over the water pipes; that cannot be helped as long as one side of the machine is connected with the earth. Another remedy which is to be adopted, is a special line of feeders attached only to the water pipes; that is, a feeder will be run from the central power house to the different parts of the city, which will not be connected with the machines at all, but will be connected with the water pipes at the central power house and with the pipes in all sections of the city. This will also materially reduce the electrolytic action.

* Abstract from a Paper read before the New England Waterworks Association.

The Telephone in Turkey.—It is said that the Sultan's fear of conspiracy has prevented the introduction of the telephone in Turkey. Not only will he not allow telephone lines to be laid in Constantinople, but he objects to them even in the other great towns, such as Smyrna and Salonica. This is so well known that for a considerable time those interested in telephone matters have ceased to apply for concessions.

PHYSICAL SOCIETY.

At the ordinary meeting of this Society, on June 9, 1893, Prof. J. Perry, F.R.S. (Vice-President), in the chair, Mr. A. P. TROTTER read a Paper on

"A New Photometer."

The author has modified his "Illuminati Ponhotometer" (described *Proc.* I.C.E., Vol. CX., Paper No. 2,619) so as to adapt it to the measurement of candle-power. The principle employed is to view a screen, illuminated by one source, through an aperture in a second screen illuminated by the other light, the aperture becoming invisible when the illuminations are equal. After using perforations of various patterns, a series of narrow slots, cut in thin paper, were found to give the best results. The plain screen is mounted behind the slotted one in a box sliding on the photometer bench, and they are arranged so that the light falls on them at equal angles. The screens are viewed from a distance of 6ft. or 7ft. through an opening in the front of the box, cords being provided for producing the traversing motion. Two "sights" set respectively at the middle of the length of the plain screen, and on the lower edge of the front opening, serve to show when the middle of the band of equal illumination is vertically above the pointer on the carriage. The photometer is found to be particularly valuable when it is desired to determine the maximum power of a variable source. When lights of different colours are being compared, say a gas flame and an arc, one end of the screen shows blue strips on a yellow ground, and the other end yellow strips on a blue ground; at the centre the colours seem to blend. To facilitate the comparison of such lights Mr. Crompton, who has been working at the subject simultaneously with the author, uses one screen tinted pale yellow and the other pale blue. Details of construction of the photometer are given in the Paper, and the accuracy attainable when comparing the equal lights of about eight candles is stated to be about 1 per cent.

Prof. S. P. THOMPSON, F.R.S., read

"Some Notes on Photometry."

The first note relates to "The Use of Two Overlapping Screens as an Isophotal," and describes the evolution of the Thompson-Starling photometer. In this instrument a prismatic block with apex upwards rests crosswise on the photometer bench, and the inclined sides are respectively illuminated by the two sources to be compared. In testing differently coloured lights, coloured stuffs were placed over the surfaces of the edge. In some cases notched and overlapping cards were used to form the overlapping surfaces. An inclination of about 70deg. between the two surfaces was found convenient. The second note refers to the "Periodic Principle in Photometry," and in it the author discusses the various methods which have been, or may be, used for producing small differences of decreasing amount between the two sides of a photometer screen. By employing a device of this kind much greater accuracy of adjustment is possible. In one form of vibration photometer, worked out by the author, the paraffin blocks of a Jolly's photometer are mounted at one end of a spring, the other end being fixed to the carriage. The act of moving the carriage starts the blocks vibrating, thus producing the desired variations.

In a third note the question of using "The Electric Arc as a Standard of Light" is dealt with. Since 1878 the positive crater has been used as a standard of whiteness, and last year both the author and Mr. Swinburne suggested that a given area of crater might be used as a standard of light. This proposal has since been carried out by M. Blondel. Since the intrinsic brilliancy of the crater is high, it necessitates very small apertures, or else the use of standards of large candle-power. Advantages of using powerful standards are pointed out in the Paper. With a circular hole 1mm. in diameter, a standard of about 55 candles could be obtained; with such a source, benches longer than usual would be preferable. At the end of the note, the errors which may be introduced by using as an arc standard a hole in a plate of sensible thickness, when viewed obliquely, are investigated, as well as those due to inaccuracy of setting the plane of a hole made in foil, perpendicular to the photometer bench.

DISCUSSION.

Major-General FESTING, in opening the Discussion on both Papers, said reflection from the sides of the hole in a thick plate would tend to lessen the error calculated by Prof. Thompson. The ordinary impurities in carbon were not likely to alter the brilliancy of the crater. Captain Abney and himself had no reason to distrust its constancy. Both the vibrating photometer and Mr. Trotter's arrangement would be very useful.

Dr. SUMPNER said his photometric experience had been obtained with the Bunsen, Jolly, and Lummer-Brodhun types. With the two former the inaccuracy arising from uncertainty of adjustment was about ½ per cent. Changes of about 0·4 per cent. (average) resulted from reversing the screens. The Lummer-Brodhun instrument (which he described) was better than either of the other two, the average error being about ¼ per cent.

Mr. FRANK WRIGHT thought scientific men gave too little attention to the question of light standards. Photometers could be relied on much more than any standard at present in use. The Methven screen was the most practical standard yet devised, but, in his opinion, no gaseous flame could be a real standard on account of the influence of the surrounding atmosphere.

Prof. AYRTON saw difficulties in using long benches as suggested by Dr. Thompson, on account of the serious atmospheric absorption which occurs with light from arcs. Decreasing the intensity by dispersion or otherwise was preferable. In some tests on glow-lamps, now being carried out at the Central Institution, a Bernstein lamp used as a standard was mounted on a spring and vibrated.

Mr. MEDLEY showed the vibrating standard referred to by Prof. Ayrton, and gave series of numbers showing that with this device, in conjunction with the Lummer-Brodhun photometer, accuracies of about ¼ per cent. were obtainable.

Mr. SWINBURNE thought Mr. Trotter's arrangement was better than the wobbling photometer. As to the best length of bench, he was inclined to think the shorter the better, provided its dimensions were large compared with that of the standard light. He concurred with Mr. Wright in his remarks about the desirability of obtaining a better standard. Speaking of the arc as a standard, he said that only impurities less volatile than carbon would influence the brightness. An important factor was the emissivity of the carbon, which might not be constant.

Mr. BLAKESLEY thought the accuracy obtainable with Mr. Trotter's photometer had been underrated, and pointed out that by using quadrant-shaped screens, intersecting orthogonally on the axis of the photometer, instead of straight ones, the width of the neutral band could be greatly diminished.

Mr. TROTTER, referring to Dr. Thompson's Paper, said he had been engaged in collaboration with Mr. Swinburne in developing the arc standard. He had found considerable difficulty in making suitable pinholes. It was not an easy matter to accurately measure the hole when made. In photometric measurements he had found it very important to reverse his screens. Curved screens, as suggested by Mr. Blakesley, had been tried, but with little advantage. They also destroyed the approximate direct-reading property of the photometer. The subject of changing the length of a bench, and its effect on the gradient of illumination, was discussed. With short benches one had to guard against departure from the inverse-square law, due to appreciable size of the standard. Recent experiments had shown that the light given out by the 1 sq. mm. of crater surface differed considerably from 70 candles.

A Paper on

"The Magnetic Field close to the Surface of a Wire conveying an Electrical Current,"

by Prof. G. M. MINCHIN, M.A., was taken as read. In this Paper the author applies the solution he gave in March last for the conical angle subtended by a circle at any point in space, to determine the magnetic potential at a point near the surface of a ring of wire of finite cross section. The shapes of the lines of force near the surface, for several laws of current distribution across the section, have also been worked out.

BOOKS RECEIVED.

"The Dynamo." By C. C. Hawkins, M.A., and F. Wallis. A.I.E.E. (London: Whittaker and Co.) 500 pp., 8vo.

Proceedings of the Royal Society. Vol. LIII., No. 322. (London: Harrison and Sons.)

"Dynamoelektrischen Maschinen." By Dr. F. Auerbach, (Leipzig: A. Hartleben.)

Journal of the Institution of Electrical Engineers. Vol. XXII., No. 106. (London: E. and F. N. Spon.)

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

WEDNESDAY, June 21st.

ROYAL METEOROLOGICAL SOCIETY.

7 p.m. Ordinary Meeting to be held at 25, Great George-street, Westminster. Papers to be read: (1) "Fifteen Years' Fog in the British Islands, 1876-1890," by Robert H. Scott, M.A., F.R.S.; (2) "Upper Currents of Air over the Arabian Sea," by W. L. Dallas, F.R.Met.Soc. Also an Address by Mr. E. D. Archibald, M.A., on "Australian Climate and Weather," illustrated by a number of Lantern Slides.

ROYAL MICROSCOPICAL SOCIETY.

8 p.m. Ordinary Meeting.

FRIDAY, June 23rd.

PHYSICAL SOCIETY.

5 p.m. Papers to be read: (1) "Exhibition of a Form of Carey-Foster Bridge," by Mr. Nalder; (2) "An Influence Machine," by Mr. Pidgeon; (3) "An Influence Machine," by Mr. Wimshurst; (4) "A New Volumenometer," by Mr. Myers.

INSTITUTION OF ELECTRICAL ENGINEERS.

9 p.m. Conversazione at the Institute of Painters in Water Colours, Piccadilly.

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 4.30 p.m. Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.*

"THE ELECTRICIAN" SERIES *at present consists of—*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.

VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free.

VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post-free.

The same in German, price 8s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING (1893). By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. [*Nearly ready.*

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. *Nearly ready.*

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. [*Nearly ready.*

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*In preparation.*

ELECTRICITY AS A MOTIVE POWER. By A. T. SNELL. [*In preparation.*

THE INCANDESCENT LAMP : Its Manufacture and Use. [*In preparation.*

Now Ready, in Two Volumes. Prospectuses Free.

"THE ELECTRICIAN" PRIMERS. *Fully Illustrated.*

Price : Stout paper covers, 2s., post free, 2s. 2d. each ; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

STEEL-PLATE PORTRAITS

Of Willoughby Smith; W. H. Preece, F.R.S. (President of the Institution of Electrical Engineers); Michael Faraday; Sir John Pender, G.C.M.G., M.P.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Patey, C.B.; Dr. John Hopkinson, F.R.S.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz; Prof. W. E. Ayrton; Lord Rayleigh, F.R.S.; Cyrus W. Field; Werner von Siemens; and Sir James Anderson, have been issued as Supplements to "THE ELECTRICIAN."

Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price 4s. 6d., carriage paid (U.K.).

ELECTRICITY SUPPLY.

The sessions of scientific societies being now closed, electrical engineers may profitably turn their attention from details, and take a glance at the general condition and prospects of the industry of electrical supply. However broadly a subject may be handled in a Paper read before an engineering meeting, the discussion which follows it is sure to tear off the vesture of generalisations, and to disclose the naked facts on which it was hung, even if the very skeleton is not laid bare by ravening critics. Fierce as is the controversy which rages between alternate-current and continuous-current partisans, they are agreed on the value and comfort of electric lighting as compared with other means of illumination, upon the usefulness and adaptability of electric motors, and the ingenuity and convenience of electrical cooking. An interesting review of the whole matter has been made by a man who, while unconnected with any system, has a much more intimate knowledge of the business of purveying light, heat, and power, to the public in their homes than the majority even of experienced electrical engineers. Mr. DENNY LANE, in his Presidential Address to the Incorporated Gas Institute, does not spare criticism, but he knows too much about electric lighting to disparage its value. If he had the chance he would put down an electric supply plant at Cork on the distribution-by-gas principle which he has long advocated, and which, if carried out by a man of his experience, might lead to most important changes both in the economics and in the management and proprietorship of supply business. In this Address, the first portion of which we print in another

Digitized by Google

column, it must be confessed that undue prominence is given to the working of the London Electric Supply Corporation. The history of its troubles is pretty well known; nothing can be learned from its present condition; but while the possibility of a fair load remains for it, there is still a possibility that it will yet do all that has been promised for it. We must demur to some statistics, a matter about which Mr. DENNY LANE is generally very careful. Basing some calculations on figures put forward by Prof. AYRTON, he makes out that the whole electric lighting of Great Britain is equivalent to 1,100 million feet of gas in the year. In this calculation he makes an assumption unworthy of the impartiality with which he usually deals with electrical matters, but one which seems to be inseparable from gas engineers, namely, that 5 cubic feet of gas yield 16 candle-power for an hour. Of course, with a Parliamentary Argand burner and proper cooking of the temperature, and other tricks well known to gas testers, 5ft. of gas may generally be induced to give this light as a maximum, but in the present comparison two candles per cubic foot is a liberal estimate for ordinary domestic burners. Electrical engineers might as well base all such calculations upon the arc lamp, which takes only a quarter of a watt per candle.

The output of the London Electric Companies alone amounted to over 7,900,000 units during last year. This comes to 250 million lamp hours of 8 c.p., and, at two candles per cubic foot, is equivalent to 1,000 million cubic feet of gas in the year. This hardly alters the final comparison, but it is worth while to take actual figures when they are to hand. The electric supply of London is, therefore, at present about one-thirtieth of the gas supply, as given by Mr. DENNY LANE, reckoned as light for light, and is only a little over one-half of the yearly increase, which Mr. LANE puts at 1,800 millions. Gas engineers know well enough that mineral oil is a far more serious competitor than the electric lamp. In not a few cases electric lighting has been simply introduced to replace oil lamps and candles, the gas bill being unaltered, or even increased.

Another very useful survey, not of electric supply as a whole, but of the various systems which are now in use, has been made by Prof. HENRY ROBINSON. Endeavouring, as he does, to hold an impartial position, he is, of course, sure to be attacked by some alternate-current men for admitting that continuous currents are worthy of any consideration; while a much smaller number of low-pressure men will think that he draws the line too close round their system, and unduly limits the area over which they can effectively and economically supply electrical energy. Prof. ROBINSON condemns the two-wire low-pressure system no less forcibly than alternate-current distribution by transformers in each house. Both are regarded as obsolete, although the latter is used, says Prof. ROBINSON, by several companies in London, whose main object in adopting it was to obtain a hold over as large an area as possible with the minimum expenditure of capital. Of the three conditions upon which the choice of a system depends, the geographical distribution of the demand is the most easy to determine. The probable demand, both at the outset and in the future, and the nature of the demand, are very difficult to estimate. An electrical engineer of experience can, by visits to a town and careful observation, arrive at some idea of these conditions, or may be able to extract information about them from some of the inhabitants. The geographical distribution readily lends itself to calculation, and it is on such data that Continental electricians delight to work out the best position for the station by considering the centre of gravity of the lights, or some such abstraction. Prof. ROBINSON seems to have had the geographical condition chiefly in view when he worked out his examples. How far the other conditions would modify these results is difficult to say. The choice of a system for the lighting of a town is more difficult when the area to be supplied includes both shops and residential districts, especially when the latter, as is often the case, more or less surround the former. A notable change in the centre of gravity of the lights occurs between five and seven in winter, and does not seem to have attracted the attention of mathematicians who have busied themselves with theoretical networks and feeders.

Engineers who are called upon suddenly to give a rough estimate for a complete central station, either straight "out of their heads" or by calculation on the back of an envelope, should be grateful to Prof. ROBINSON for the simple formulæ proposed by him. The cost, he says, is £2,500 + £45 to £50 per kilowatt, according to circumstances. Turning to Dr. HOPKINSON'S estimate in his Presidential Address to the Junior Engineering Society last November, we find that a station to deliver 2,500 kilowatts should cost, without land, £120,000. Dr. HOPKINSON gave no idea of the length and size of mains and feeders, for which he set down £50,000. Working backwards to Prof. ROBINSON'S formula, we get £2,500 + £46·8, a remarkable confirmation of its general accuracy. The difficulty, of course, with such a formula is the extent of the mains and the cost of land. Taking St. Pancras station at 850 kilowatts output, the mains alone come to £2,500 + £36·8 per kilowatt; but Prof. ROBINSON expressly excludes distributing mains from his calculations. Individual contractors may find that Prof. ROBINSON'S figures are not in accord with their own experience; but his method of arriving at an estimate is well worth careful attention.

REVIEWS.

Téléphonie Pratique. Par L. MONTILLOT, Inspecteur des Postes et des Télégraphes. (Paris: A. Grélot.)

We have here a lengthy and comprehensive treatise on the practice and theory of telephones and telephonic engineering; and one which, although to a large extent dealing with foreign types of instruments and Continental methods of using them, will, we are sure, be welcomed in this country by those who are interested in telephone practice. The early chapters deal briefly with the theory of sound transmission, with various kinds of primary cells, and with the microphone and Bell receiver. Sufficient explanation seems scarcely to be given of the very important use which the induction coil has in the electrical transmission of sound. We have next the inevitable permutations and combinations of microphones, each of which is dignified by the name of some "inventor," and the sundry modifications of the Bell receiver, which are similarly distinguished. Chapters VI. to XIV., on telephone lines, accessory apparatus, and telephone offices or exchanges, are the most valuable in the whole book, and, indeed, they occupy the greater part of it. The value of these chapters is enhanced by a number of well executed diagrams of the various arrangements of the circuit. Following these, a brief chapter on faults and disturbances in the line and at the various stations contains some very useful information of a practical kind. After this comes a lengthy chapter on the French legislative side of telephone work, which is largely historical. The chapter contains an interesting table of telephone circuits in all the departments of France, up to the end of 1891, with particulars of the number of subscribers, &c. The work concludes with a chapter on the application of the telephones to various scientific and industrial purposes.

How to Manage the Dynamo. By S. R. BOTTONE. (London: Whittaker and Co.)

A dynamo must be a very easy thing to manage if all that is to be said on the subject can be put, without compression,

Digitized by Google

into so small a pamphlet as the one before us. A few introductory remarks on what a dynamo is, a short chapter on the ceremony of "installating" a dynamo, followed by a second chapter on what to do if the dynamo will not work after it is installed, and a short glossary, comprise the entire work. But it is evident, from the nature of the information, that Mr. Bottone has only very little dynamos in his mind's eye, and seeks to give information to amateurs or those who may be called upon to take charge of a small electric lighting plant. The introductory remarks consist of the usual explanations of series, shunt, and other dynamos, and of the uses of the various parts of a machine. The chapter on putting down the machine and driving engine does not cover the whole ground of the subject, and a person really ignorant of the subject would probably find the information inadequate. Not a word is said about connecting up the circuit and regulating apparatus to the dynamo. The chapter on the defects inherent to dynamos is on the whole good; but the advice which is given, should the dynamo refuse to start working, is of doubtful value. The practice of tickling a dynamo into action by momentarily short circuiting the terminals with a short piece of cable, is risky, is damaging to the binding posts, and does not really get at the root of the defect in the machine. Of course, if a dynamo will not magnetise, it is very provoking, but momentarily short-circuiting the machine does not really cure the defect, and in the hands of an unskilled person there is great chance of the armature being destroyed. We have seen a piece of cable electrically welded to the terminals by such an operation as that described, making the short circuit a good permanent job. The glossary of electrical terms ought to be useful; but we would recommend Mr. Bottone to provide two distinct definitions for magnetic and for electrostatic induction, instead of lumping the two together into one.

ON LIGHT AND OTHER HIGH-FREQUENCY PHENOMENA.*

BY NIKOLA TESLA.

(Concluded from page 156.)

I noticed that small variations in the density of the air produced a considerable difference in the degree of incandescence of the

FIG. 23.—Curious Incandescence of a Wire.

wires, and I thought that, since in a tube, through which a luminous discharge is passed, the gas is generally not of uniform density; a very thin wire contained in the tube might be rendered incandescent at certain places of smaller density of the gas, while it would remain dark at the places of greater density, where the convection would be greater and the bombardment less intense. Accordingly, a tube, *t*, was prepared, as illustrated in Fig. 23, which contained through the middle a very fine platinum wire, *w*. The tube was exhausted to a moderate degree, and it was found that when it was attached to the terminal of a high-frequency coil the platinum wire *w* would, indeed, become incandescent in patches, as illustrated in Fig. 23. Later a number of these tubes with one or more wires, were prepared, each showing this result. The effect was best noted when the striated discharge occurred in the tube, but was also produced when the striæ were not visible, showing that, even then, the gas in the tube was not of uniform density. The position of the striæ was generally such, that the rarefactions corresponded to the places of incandescence or greater brightness on the wire *w*. But in a few instances it was noted that the bright spots on the wire were covered by the dense parts of the striated discharge, as indicated by *l* in Fig. 23, though the effect was barely perceptible. This was explained in a plausible way by assuming that the convection was not widely different in the dense and rarefied places, and that the bombardment was greater on the dense places of the striated discharge. It is, in fact, often observed in bulbs, that under certain conditions a thin wire is brought to higher incandescence when the air is not too highly rarefied. This is the case when the potential of the coil is not high enough for the vacuum, but the result may be attributed to many different causes. In all cases this curious phenomenon of incandescence disappears when the tube, or rather the wire, acquires throughout a uniform temperature.

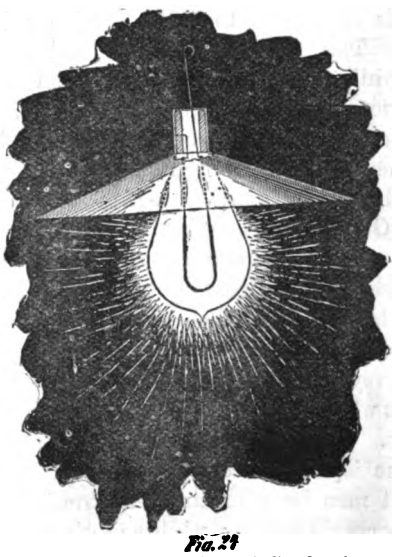

FIG. 24

Utilising the Heating Effect of Conduction Current and Bombardment.

Illustrating Lateral Diffusion.

Disregarding now the modifying effect of convection, there are then two distinct causes which determine the incandescence of a wire or filament with varying currents, that is, conduction current and bombardment. With steady currents, we have to deal only with the former of these two causes, and the heating effect is a minimum, since the resistance is least to steady flow. When the current is a varying one, the resistance is greater, and hence the heating effect is increased. Thus, if the rate of change of the current is very great, the resistance may increase to such an extent that the filament is brought to incandescence with inappreciable currents, and we are able to take a short and thick block of carbon or other material and bring it to bright incandescence with a current incomparably smaller than that required to bring to the same degree of incandescence an ordinary thin lamp filament with a steady or low-frequency current. This result is important, and illustrates how rapidly our views on these subjects are changing, and how quickly our field of knowledge is extending. In the art of incandescent lighting, to view this result in one aspect only, it has been commonly considered as an essential requirement for practical success, that the lamp filament should be thin and of high resistance. But now we know that the resistance to the steady flow of the filament does not mean anything; the filament might as well be short and thick; for if it be immersed in rarefied gas it will become incandescent by the passage of a small current. It all depends on the frequency and potential of the currents.

I have contrived an experiment which illustrates, in an interesting manner, the effect of lateral diffusion. If a very long tube

* Abstract of a lecture delivered before the Franklin Institute, at Philadelphia, February 24, 1893, and before the National Electric Light Association, at St. Louis, Mo., March 1, 1893. We are indebted to the *Electrical World*, of New York, for the blocks illustrating this lecture.

Digitized by Google

is attached to the terminal of a high-frequency coil, the luminosity is greatest near the terminal, and falls off gradually towards the remote end. This is more marked if the tube is narrow.

A small tube about ½in. in diameter and 12in. long (Fig. 25) has one of its ends drawn out into a fine fibre *f* nearly 3ft. long. The tube is placed in a brass socket T, which can be screwed on the terminal T_1 of the induction coil. The discharge passing through the tube first illuminates the bottom of the same, which is of comparatively large section; but through the long glass fibre the discharge cannot pass. But gradually the rarefied gas inside becomes warmed and more conducting and the discharge spreads into the glass fibre. This spreading is so slow that it may take half a minute or more until the discharge has worked through up to the top of the glass fibre, then presenting the appearance of a strongly luminous thin thread. By adjusting the potential at the terminal the light may be made to travel upwards at any speed. Once, however, the glass fibre is heated the discharge breaks through its entire length instantly. The interesting point to be noted is that, the higher the frequency of the currents, or, in other words, the greater relatively the lateral dissipation, at a slower rate may the light be made to propagate through the fibre. This experiment is best performed with a highly exhausted and freshly made tube. When the tube has been used for some time the experiment often fails. It is possible that the gradual and slow impairment of the vacuum is the cause. This slow propagation of the discharge through a very narrow glass tube corresponds exactly to the propagation heat through a bar warmed at one end. The quicker the heat is carried away laterally the longer time it will take for the heat to warm the remote end. When the current of a low frequency coil is passed through the fibre from end to end, then the lateral dissipation is small and the discharge instantly breaks through almost without exception.

Incandescence of a Solid.

Phosphorescence.

Incandescence or Phosphorescence of Rarefied Gas.

Luminosity of Gas at Ordinary Pressure.

Illustrating Four Kinds of Light Effects Produced by High Frequency Currents of High Potential.

After these experiments and observations which have shown the importance of the discontinuity or atomic structure of the medium, and which will serve to explain, in a measure at least, the nature of the four kinds of light effects producible with these currents, I may now give you an illustration of these effects. For the sake of interest I may do this in a manner which to many of you might be novel. You have seen before that we may now convey the electric vibration to a body by means of a single wire or conductor of any kind. Since the human frame is conducting I may convey the vibration through my body.

First, as in some previous experiments, I connect my body with one of the terminals of a high-tension transformer, and take in my hand an exhausted bulb which contains a small carbon button mounted upon a platinum wire leading to the outside of the bulb, and the button is rendered incandescent as soon as the transformer is set to work (Fig. 26). I may place a conducting shade on the bulb, which serves to intensify the action, but is not necessary. Nor is it required that the button should be in conducting connection with the hand through a wire leading through the glass, for sufficient energy may be transmitted through the glass itself by inductive action to render the button incandescent.

Next I take a highly exhausted bulb, containing a strongly phosphorescent body, above which is mounted a small plate of aluminum on a platinum wire leading to the outside, and the currents flowing through my body excite intense phosphorescence in the bulb (Fig. 27). Next, again, I take in my hand a simple exhausted tube, and in the same manner the gas inside the tube is rendered highly incandescent or phosphorescent (Fig. 28). Finally, I may take in my hand a wire, bare or covered with thick insulation, it is quite immaterial; the electric vibration is so intense as to cover the wire with a luminous film (Fig. 29).

In the first place, I will consider the incandescence of a button or of a solid in general, and dwell upon some facts which apply equally to all these phenomena. It was pointed out before that when a thin conductor, such as a lamp filament, for instance, is connected with one of its ends to the terminal of a transformer of high tension, the filament is brought to incandescence partly by a conduction current and partly by bombardment. The shorter and thicker the filament the more important becomes the latter, and finally, reducing the filament to a mere button, all the heating must practically be attributed to the bombardment. So in the experiment before shown, the button is rendered incandescent by the rhythmical impact of freely movable small bodies in the bulb. These bodies may be the molecules of the residual gas, particles of dust or lumps torn from the electrode; whatever they are, it is certain that the heating of the button is essentially connected with the pressure of such freely movable particles, or of atomic matter in general in the bulb. The heating is the more intense the greater the number of impacts per second and the greater the energy of each impact. Yet the button would be heated also if it were connected to a source of a steady potential. In such a case electricity would be carried away from the button by the freely movable carriers or particles flying about, and the quantity of electricity thus carried away might be sufficient to bring the button to incandescence by its passage through the latter. But the bombardment could not be of great importance in such case. For this reason it would require a comparatively very great supply of energy to the button to maintain it at incandescence with a steady potential. The higher the frequency of the electric impulses the more economically can the button be maintained at incandescence. One of the chief reasons why this is so, is, I believe, that with impulses of very high frequency there is less exchange of the freely movable carriers around the electrode, and this means than in the bulb the heated matter is better confined to the neighbourhood of the button.

In regard to the incandescence of a refractory button (or filament) in an exhausted receiver, which has been one of the subjects of this investigation, the chief experiences which may serve as a guide in constructing such bulbs, may be summed up as follows: (1) The button should be as small as possible, spherical of a smooth or polished surface, and of refractory material which withstands evaporation best; (2) The support of the button should be very thin and screened by an aluminium and mica sheet, as I have described on another occasion; (3) The exhaustion of the bulb should be as high as possible; (4) The frequency of the currents should be as high as practicable; (5) The currents should be of a harmonic rise and fall without sudden interruptions; (6) The heat should be confined to the button, by inclosing the same in a small bulb or otherwise; (7) The space between the walls of the small bulb and the outer globes should be highly exhausted.

Most of the considerations which apply to the incandescence of a solid just considered may likewise be applied to phosphorescence. Indeed, in an exhausted vessel the phosphorescence is, as a rule, primarily excited by the powerful beating of the electrode stream of atoms against the phosphorescent body. Even in many cases, where there is no evidence of such a bombardment, I think that phosphorescence is excited by violent impacts of atoms, which are not necessarily thrown off from the electrode, but are acted upon from the same inductivity through the medium, or through chains of other atoms.

Coming now to the most interesting of these phenomena, the incandescence or phosphorescence of gases, at low pressures or at

Digitized by Google

the ordinary pressure of the atmosphere, we must seek the explanation of these phenomena in the same primary causes, that is, in shocks or impacts of the atoms. Just as molecules or atoms beating upon a solid body excite phosphoresence in the same or render it incandescent, so when colliding among themselves they produce similar phenomena. But this is a very insufficient explanation, and concerns only the crude mechanism. Light is produced by vibrations which go on at a rate almost inconceivable. If we compute, from the energy contained in the form of known radiations in a definite space the force which is necessary to set up such rapid vibrations, we find, that though the density of the ether be incomparably smaller than that of any body we know, even hydrogen, the force is something surpassing comprehension. What is this force, which in mechanical measure may amount to thousands of tons per square inch? It is electrostatic force in the light of modern views. It is impossible to conceive how a body of measurable dimensions could be charged to so high a potential that the force would be sufficient to produce these vibrations. Long before any such charge could be imparted to the body it would be shattered into atoms. The sun emits light and heat, and so does an ordinary flame or incandescent filament, but in neither of these can the force be accounted for if it be assumed that it is associated with the body as a whole. Only in one way may we account for it, namely, by identifying it with the atom. An atom is so small, that if it be charged by coming in contact with an electrified body, and the charge be assumed to follow the same law as in the case of bodies of measurable dimensions, it must retain a quantity of electricity which is fully capable of accounting for these forces and tremendous rates of vibration. But the atom behaves singularly in this respect; it always takes the same "charge."

Fig. 32

Electrostatic Action Between Primary and Secondary, with Extremely High Frequencies.

We then must ask ourselves: How can free molecules or atoms be affected? It is a fact that they can be affected by electrostatic force, as is apparent in many of these experiments. By varying the electrostatic force we can agitate the atoms, and cause them to collide under evolution of heat and light. It is not demonstrated beyond doubt that we can affect them otherwise. If a luminous discharge is produced in a closed exhausted tube, do the atoms arrange themselves in obedience to any other but to electrostatic force acting in straight lines from atom to atom? Only recently I investigated the mutual action between two circuits with extreme rates of vibration. When a battery of a few jars (*cccc*, Fig. 32) is discharged through a primary P of low resistance (the connections being as illustrated in Figs. 19*a*, 19*b*, and 19*c*), and the frequency of vibration be many millions, there are great differences of potential between points on the primary not more than a few inches apart. These differences may be 10,000 volts per inch, if not more, taking the maximum value of the E.M.F. The secondary *s* is, therefore, acted upon by electrostatic induction, which is in such extreme cases of much greater importance than the electro-dynamic. To such sudden impulses the primary as well as the secondary are poor conductors, and therefore, great differences of potential may be produced by electrostatic induction between adjacent points on the secondary. Then sparks may jump between the wires and streamers become visible in the dark if the light of the discharge through the spark gap *d d* be carefully excluded. If, now we substitute a closed vacuum tube for the metallic secondary *s*, the differences of potential produced in the tube by electrostatic induction from the primary are fully sufficient to excite portions of it; but as the points of certain differences of potential on the primary are not fixed, but are generally constantly changing in position, a luminous band is produced in the tube, apparently not touching the glass, as it should, if the points of maximum and minimum differences of potential were fixed on the primary. I do not exclude the possibility of such a tube being excited only by electro-dynamic induction, for very able physicists hold this view; but, in my opinion, there is as yet no positive proof given that atoms of a gas in a closed tube may arrange themselves in chains under the action of an electromotive impulse produced by electro-dynamic induction in the tube. I have been unable so far to produce striæ in a tube, however long, and at whatever degree of exhaustion, that is, striæ at right angles to the supposed direction of the discharge or the axis of the tube, but I have distinctly observed in a large bulb, in which a wide luminous band was produced by passing a discharge of a battery through a wire surrounding the bulb, a circle of feeble luminosity between two luminous bands, one of which was more intense than the other. Furthermore, with my present experience I do not think that such a gas discharge in a closed tube can vibrate, that is, vibrate as a whole. I am convinced that no discharge through a gas can vibrate. The atoms of a gas behave very curiously in respect to sudden electric impulses. The gas does not seem to possess any appreciable inertia to such impulses, for it is a fact that the higher the frequency of the impulses, with the greater freedom does the discharge pass through the gas. If the gas possesses no inertia, then it cannot vibrate, for some inertia is necessary for the free vibration. I conclude from this that if a lightning discharge occurs between two clouds, there can be no oscillation, such as would be expected, considering the capacity of the clouds. But if the lightning discharge strike the earth, there is always vibration—in the earth, but not in the cloud. In a gas discharge each atom vibrates at its own rate; but there is no vibration of the conducting gaseous mass as a whole. This is an important consideration in the great problem of producing light economically, for it teaches us that to reach this result we must use impulses of very high frequency, and necessarily also of high potential.

Much would remain to be said about the luminous effects produced in gases at low or ordinary pressures. With the present experiences before us, we cannot say that the essential nature of these charming phenomena is sufficiently known. But investigations in this direction are being pushed with exceptional ardour. Every line of scientific pursuit has its fascinations, but electrical investigation appears to possess a peculiar attraction, for there is no experiment or observation of any kind in the domain of this wonderful science which would not forcibly appeal to us. Yet to me it seems that, of all the many marvellous things we observe, a vacuum tube, excited by an electric impulse from a distant source, bursting forth out of the darkness and illuminating the roam with its beautiful light, is as lovely a phenomenon as can greet our eyes. Viewed from a distance the effect is weak, and much of its beauty is lost, but being near, or holding the tube in one hand, one cannot resist its charm.

In presenting these insignificant results I have not attempted to arrange and co-ordinate them as would be proper in a strictly scientific investigation, in which every succeeding result should be a logical sequence of the preceding, so that it might be guessed in advance by the careful reader or attentive listener. I have preferred to concentrate my energies chiefly upon advancing novel facts or ideas which might serve as suggestions to others, and this may serve as an excuse for the lack of harmony. The explanations of the phenomena have been given in good faith, and in the spirit of a student prepared to find that they admit of better interpretation. There can be no great harm in a student taking an erroneous view; but when great minds err, the world must dearly pay for their mistakes.

COMPARISONS BETWEEN THE DIFFERENT SYSTEMS OF DISTRIBUTING ELECTRICITY.

BY PROF. H. ROBINSON.

In advising various authorities as to the most suitable system for an installation of electric lighting in their districts, I have found it impossible to give, in a report of moderate length, the reasons which lead to the conclusions and opinions contained therein. I have therefore thought it would be useful to authorities whom I am advising, if I set forth in a separate statement the data which govern the consideration of the subject. In comparing the different systems of electric lighting, it is indispensably necessary that the data should be based on conditions which are those that are likely to arise in practice, and on estimates worked out on equally liberal scales of prices.

The choice of a system depends upon the following conditions:—

(*a*) The probable demand, both at the outset and in the future.

(*b*) The geographical distribution of the demand.

(*c*) The nature of the demand, and the length of time during which the current is likely to be required.

The systems may be divided into two classes:—

I. The "Continuous Current."

II. The "Alternating Current."

The term "Continuous Current" is applied to a current which is passed continuously in one direction through the lamps, while with the "Alternating Current" the direction of the current is reversed generally about one hundred times per second. Both systems produce the same amount of light from a given amount of

Digitized by Google

energy actually expended in the lamps. The difference between the systems lies in the manner of conveying the energy from the central station to the lamps.

The ordinary incandescent electric lamp can only be worked at pressures not exceeding 110 volts, and it is not economical to convey current long distances at such a low pressure As a general proposition it may be stated that the higher the pressure the more economically can the electrical energy be conveyed from one point to another. One way of increasing the working pressure is to place two lamps in "series" and then to distribute the current at 220 volts pressure instead of 110. This is the principle of what is called "The Three-wire System," and it can be applied to both continuous and alternating-current distribution. The same principle may be extended by placing three or four lamps in "series" and raising the pressure to 330 or 440 volts, this latter being called the "Five-wire System."

Another way of increasing the pressure to economise in the distribution, is to generate the current at very high pressures, and to transmit it at this high pressure from the central station to some point near the lamps, and there to "transform" it down to the low pressure suitable for working the lamps With the continuous current the "transformation" can be effected by employing a high-tension current to work a motor, which drives a dynamo to generate another current at the required low pressure. These transformers can be made to give out, at low pressure, from 81 to 85 per cent. of the energy that is supplied to them at high pressure when working at full load, but at lighter loads the efficiency is much less.

Alternating currents can be transformed from one pressure to another by a "Transformer" or "Converter," which consists of two coils of wire wound through a core of iron plates or strips. The high-tension current passes through one coil, and the reversals of direction in the current induce certain magnetic changes in the iron core, which, in turn, induce another alternating current in the second coil of wire, the relative pressures of the two currents depending upon the proportions of the two coils of wire. These transformers are much more efficient and much cheaper than continuous-current transformers. Small transformers, sufficient to work lamps in one private house, can be made to give an efficiency of about 93 per cent. at full load; and large transformers, sufficient to serve 25 houses or more, can be made to give an efficiency of about 97½ per cent. at full load.

The current in the primary coil varies as lamps are connected to the secondary coil, but if all the lamps are switched off there is still a certain loss going on so long as the transformer is connected to the primary mains. The perpetual waste of power amounts to 3½ or 4 per cent. of the full load in small house tranformers, but with very large sizes the waste can be reduced to about 1 per cent. of the full load

The continuous-current and the alternating-current systems may be divided under the following heads:—

CONTINUOUS CURRENT.

A. Two-wire system. Direct supply at 110 volts or less.
B. Three-wire system. Direct supply at about 220 volts.
C. Five-wire system. Direct supply at about 440 volts.
D. Continuous-current Transformer System. Current generated at about 1,000 volts, and transformed at sub-stations to feed into low-tension distributing mains.

Note.—Storage batteries may be used in combination with any of the foregoing.

ALTERNATING CURRENT.

A. The House Transformer System. Current generated at from 1,000 to 2,500 volts, and transformed down to 50 or 100 volts by small transformers placed on each consumer's premises.

B. The Sub-station Transformer System. Current generated at 1,000 to 2,500 volts, and transformed at sub-stations by large transformers feeding into low-tension distributing mains.

Note.—As storage batteries cannot be charged with alternating currents, the machinery must be kept running continuously, whether there is a profitable demand to meet or not. The alternating current is not so satisfactory for motive power as the continuous current.

The "Distributing Mains" are those to which the house connections are made, and the "Feeders" are conductors carrying current from the generating station to distant points on the distributing mains without having any current drawn off *en route*. The pressure in the distributing mains has to be kept constant within a small percentage, and it is found more economical to work the feeders with a larger percentage of variation, the pressure being regulated according to the amount of current passing, so as to maintain the required standard pressure at the distant points where the distributing mains are fed.

Where high-tension currents are used and transformed at sub-stations, the high-tension conductors may be regarded as "Feeders."

CONTINUOUS-CURRENT SYSTEM A.

The continuous-current system A (namely, the two-wire direct supply) is suitable only for private installations and for very small districts. Practically speaking, it may be left out of consideration in dealing with the distribution of electricity over districts or towns.

CONTINUOUS-CURRENT SYSTEM B.

The continuous-current system B (namely, the three-wire direct supply at about 220 volts) is the most usual method of employing continuous current. It is very economical and easy to work where the *average** length of feeders is less than three-quarters of a mile.

CONTINUOUS-CURRENT SYSTEM C.

The continuous-current system C may be used with advantage where there is a large demand at an average distance not exceeding one mile from the central station. It is a little more complicated than the three-wire system, and requires special arrangements for regulating the pressure which are somewhat costly in comparison to those of the three-wire system, unless the demand is very large, in which case the cost becomes insignificant.

CONTINUOUS-CURRENT SYSTEM D.

The continuous-current system D cannot compete with others by itself, but it is very useful in combination with the three-wire system to serve outlying portions of a district where the demand is small.

ALTERNATING-CURRENT SYSTEM A.

The alternating-current system A may be used with advantage only where the demand is distributed over a very straggling district, and where the lights are required for long periods of time. The perpetual waste going on in small transformers is a very serious drawback to this system in any place where coal is expensive. In the case of a demand arising chiefly in shops, the all-year-round efficiency of distribution is only about 66 per cent., so that the central station plant has to generate about 50 per cent. more energy than the lamps actually require. In a residential district the all-year-round-efficiency is even less. It may be taken that at the present time private consumers use their lamps only for from 100 to 400 hours per annum, and the probability is that the general average will tend towards the lower figure as people learn to economise by switching off lights when they are not actually required. This tendency is fatal to economy in supply by the house-transformer system in residential districts. Taking the demand as equivalent to 400 hours run per annum at full load (which demand is spread over about 2,000 hours in varying proportions), the all-year-round efficiency works out at only 54 per cent., consequently for every 1,000 units delivered to the lamps, 1,850 units have to be generated by the central station plant. Again, taking a demand equivalent to 100 hours' run per annum at full load, the all-year-round efficiency comes out at only 23 per cent., so that the central station plant would have to generate more than four times as much energy as the lamps require. The only argument in favour of the adoption of this system is in the smaller capital outlay involved owing to the absence of costly low-tension distributing mains, and, consequently, in the facility with which a small demand that is scattered over a straggling district can be met with a moderate capital outlay. This system, however, cannot possibly compete with other systems in the long run, and for populous districts it may be practically regarded as being quite obsolete, although it is used by several companies in London, whose main object in adopting it was to obtain a hold over as large an area as possible with the minimum expenditure of capital.

ALTERNATING-CURRENT SYSTEM B.

The alternating-current system B is a very great improvement on the first, the superiority being entirely due to the use of large transformers in place of small ones, and in supplying a large number of consumers from one transformer, which need not be capable of serving simultaneously the total number of lamps installed, whereas a transformer in a house must be capable of serving the whole of the lights simultaneously, although it may only be required to do so once or twice a year. The aggregate demand in a district never exceeds 75 per cent. of the lamps installed, and in some districts (particularly residential districts) only one-half or a third of the lamps are ever used simultaneously; the result is that, whereas there is a perpetual waste in the house transformer system representing 3½ or 4 per cent. of the power required to run all the lamps simultaneously, there is in the sub-station transformer system a perpetual waste of only about 1 per cent. of the power required to run from one-third to three-fourths of the lamps simultaneously.

The low-tension distributing mains may be laid on the three-wire system. They cost about the same as similar mains for continuous

* The term "average length of feeders" is used to mean the average distance travelled by the current before being delivered into the distributing mains. The maximum length of feeder may be double the average, or even more, and the most distant lamps may be 300 or 400 yards beyond the end of the longest feeder. This point is frequently lost sight of in comparing high and low-tension systems, and erroneous conclusions are arrived at, owing to calculations based on the *maximum* length of feeder being taken in place of the *average* as defined above.

Digitized by Google

current, or slightly more, owing to the necessity for surrounding the conductors with an iron case to prevent the alternating current affecting any neighbouring telephone or telegraph wires. For the purposes of a general comparison between the best alternating-current system and the best continuous-current system, it may be assumed that both of them require a network of low-tension distributing mains, which will be approximately equal in cost.

In some instances it may be desirable to combine the house transformer system with the sub-station transformer system, using the former to serve small demands in outlying parts of a district in which the bulk of the supply is served by the latter system.

In cases where the average length of feeders exceeds one mile, the alternating transformer sub-station system is undoubtedly the most economical for electric lighting purposes; but the question arises as to whether it is economical in any instance to serve a district with a central station so far away from the demand. This resolves itself into the consideration of the question as to whether it is economical to serve a large district entirely from one station, or from two or more smaller stations. It is very frequently asserted that the cost of running one station is much less than the cost of running two or more of the same aggregate power, and also that by using high-tension currents the station may be placed in some very favourable position for obtaining coal, water, &c., which may be far removed from the centre of the district to be served. These advantages have been, and still are, greatly exaggerated, and entirely fallacious views are put forward about them. In some instances the site for a station has been chosen with a view to save from 10 to 20 per cent. in the price of coal delivered, when eventually the cost of coal consumed turns out to be greater, owing to the greater losses in distribution. Interest on the extra capital, and depreciation, &c., on the main feeders, will often exceed the anticipated saving due to cheaper coal.

With a view to give a clear idea as to the best system to use in particular cases, some examples will be given.

The capacity of the station is stated in kilowatts. One kilowatt is capable of delivering one Board of Trade unit per hour to the lamps. Thus a 300 kilowatt station means one which can deliver 300 units per hour to the lamps.

One Board of Trade unit is sufficient to work a 16 c.p. lamp for 17 or 18 hours, consequently the number of lamps which a station can serve simultaneously may be found by multiplying the kilowatts by 17 or 18. Thus a 300 kilowatt station will serve 5,100 to 5,400 lamps of 16 c.p. simultaneously; this may represent from 6,800 to 10,000 or more lamps, fixed according to the character of the district.

Example No. 1.

Average length of feeders, less than ¾ mile.
Service required, 1,000 kilowatts or less.

The most economical system in total annual cost (*i.e.*, including interest on capital, working expenses, maintenance, and depreciation) is the continuous-current three-wire system, with a small reserve of storage batteries to maintain the supply during periods of light load.

The alternating system can be carried out at a slightly less capital cost if the average length of the feeders exceeds 600 yards; but the working expenses are so much greater that the total annual cost exceeds that of a continuous-current system.

Example No. 2.

Average length of feeders, less than ¾ mile.
Service required, 1,000 to 2,000 kilowatts.

The most economical system will be the three-wire or five-wire continuous-current systems, with or without a reserve of storage batteries for the light load.

Example No. 3.

Average length of feeders, from ¾ to 1 mile.
Service required, 2,000 kilowatts or more.

The most economical system will be the five-wire system. The alternating transformer system comes second, and the three-wire continuous-current third, in order of economy in total annual cost. The alternating system would cost slightly less than the five-wire system in capital outlay, but this is more than counterbalanced by the heavier working expenses of the alternating system.

Example No. 4.

Average length of feeders, more than 1 mile.
Service required, 200 kilowatts or more.

The most economical system, both in capital cost and in total annual cost, will be the alternating transformer system.

Note.—If the demand exceeds 1,500 kilowatts, it would be cheaper to serve this district with two or more stations instead of one, as shewn in Example No. 6.

Example No. 5 (A *and* B).

A district about 2½ miles long, requiring a service of 300 kilowatts.

5 A. If at least two-thirds of the demand can be served direct from the central station with feeders *averaging* not more than half a mile in length, the most economical system would be the continuous-current three-wire system, combined with continuous current transformer sub-stations to serve the small demand at a distance of more than one mile, and with a reserve of storage batteries to serve the light load work. In special cases it might be better to use the three-wire direct supply throughout, with the batteries placed in sub-stations at the ends of the longest feeder.

5 B. If only one-third of the demand can be reached by feeders averaging half a mile in length, the alternating-current system would be the best, as the saving in interest on capital, &c., will be sufficient to overbalance the cost of running the machinery continuously.

Example No. 6.

A district about three miles long requires a service of 1,250 kilowatts at the outset, increasing to 2,500 kilowatts in a few years and afterwards to 5,000 kilowatts.

Leaving out of consideration the low-tension distributing mains, which would be required for both continuous and alternating systems, the following comparison is based upon the cost of central stations, feeders, and sub-stations, as regards capital and interest on that capital, depreciation of the works, cost of energy wasted in distribution, and additional cost of wages involved by working mere than one station.

The cost of central stations is taken to be £2,500+£45 per kilowatt for the alternating-current system. For the continuous-current system it is taken at £2,500+£50 per kilowatt with feeders averaging half a mile long, and £2,500+£46 per kilowatt with feeders averaging one quarter of a mile long. The difference is due to the inferior efficiency of the continuous-current system at full load when the feeder exceeds one quarter of a mile in length. In both cases, however, the extra capital required to erect two stations in place of one is about £2,500. The cost of continuous-current feeders half a mile long is about £14 per kilowatt, and the cost of high-tension alternating current feeders half a mile long is about £8 per kilowatt, and the sub-stations with alternating transformers cost about £6 per kilowatt. Interest on capital is taken at 5 per cent., depreciation at 6 per cent. on central stations, 2½ per cent. on feeders, and 15 per cent. on alternating transformers. The extra wages and miscellaneous expenses involved by working two stations instead of one are taken at £750 per annum. The output is calculated on a "load factor" of 10 per cent., which is equivalent to a run of 880 hours per annum at full load. The all-year-round efficiency of distribution is taken at 88 per cent. for the alternating-current system, and 95 per cent. for the continuous-current system, with feeders averaging half-a-mile long. The cost of the energy wasted in distribution is taken at 2d. per Board of Trade unit. It is assumed that the average length of the feeders will be one mile, if the district is served from one station; half-a-mile if it is served from two stations; and one-third of a mile if it is served from three stations.

The following table gives the capital outlay in respect of central stations, sub-stations, and feeders, and the total annual cost of all the above-mentioned items which affect the comparison:—

	Capital outlay. £	Annual cost. £
1,250 kilowatt service:—		
*One alternating-current station	86,250	10,760
Two alternating-current stations	78,750	11,040
†Two continuous-current stations	85,000	9,990
Three continuous-current stations	81,900	10,470
2,500 kilowatt service:—		
One alternating-current station	170,000	21,250
*Two alternating-current stations	152,500	20,775
Two continuous-current stations	165,000	18,675
†Three continuous-current stations	156,300	18,520
5,000 kilowatt service:—		
One alternating-current station	337,500	42,175
*Two alternating-current stations	300,000	40,250
*Three alternating-current stations	289,200	40,280
Two continuous-current stations	325,000	36,050
†Three continuous-current stations	305,100	34,730

* The best arrangements with alternating current.
† The best arrangements with continuous current.

An examination of the above table will show that the 1,250 kilowatt service can be carried on more economically, both as regards capital outlay and annual cost, by two continuous-current stations than by one alternating-current station.

The 2,500 kilowatt service can be carried on by two alternating-current stations more economically than by one alternating-current station, and still more economically by two or three continuous-current stations.

The 5,000 kilowatt service can be carried on by two or three alternating-current stations better than by one alternating-current station; but the work could be very much more economically performed by three continuous-current stations.

In every case, therefore, it is clear that a district of this magnitude can be supplied by two or three continuous-current stations

Digitized by Google

more economically than by any alternating-current system. Moreover, the capital outlay for the best arrangement with the alternating system differs very slightly from that of the best continuous-current arrangement, and where the alternating-current capital comes out the smaller of the two, the saving in annual cost by the continuous-current system will entirely cover the difference in less than three years. In this comparison the continuous current has been calculated on the three-wire system throughout. The 5,000 kilowatt service could, however, be more economically worked by the five-wire system, which can be introduced and grafted on to what was previously the three-wire system without the slightest difficulty. The capital cost with that arrangement would then be considerably less than with the alternating-current system, and the annual saving would be more than £6,000.

The output has been assumed to be the same for the two systems, but there is very little doubt that an installation for electric lighting on the continuous-current system has a much better future for motive-power purposes than one that is on the alternating-current system. At the present time the question of motive power is coming to the front, and will be a very important branch of the business of electric supply undertakings when the works reach a sufficiently large size to enable the price of the current to be reduced below 6d. per unit as a maximum price, and to permit the introduction of a sliding scale of charges which would work out to less than 3d. per unit for consumers who require current all day long. The continuous-current system has a large field for remunerative business in this direction, as there is great competition in the manufacture of thoroughly satisfactory electric motors, whereas the same cannot be said of alternating-current motors.

Another very strong reason for preferring continuous current is that it can be used for charging storage batteries, and they open another field for augmenting the "load factor" on the central station which is not open to alternating-current systems.

Batteries in Sub-stations, to assist during Periods of Maximum Demand.

A continuous-current station, with feeders averaging half-a-mile in length, costs from £65 to £70 per kilowatt for central-station plant and feeders on the average, but the longest distance service (¾ mile to 1 mile from the station) costs from £85 to £100 per kilowatt. In such cases it becomes a question whether batteries cannot be profitably used in sub-stations to augment the capacity of the long-distance service plant and feeders.

Battery sub-stations can be erected and fitted with all the necessary appliances for charging and discharging at a cost of £100 per kilowatt, taking the period of discharge as 10 hours. The same batteries can be discharged at double the rate for four hours, so on this basis the cost is only £50 per kilowatt. It is not probable that the maximum load would ever remain on the station for more than six hours continuously. For the purposes of the following comparison, it is assumed that the cost of battery stations would be £70 per kilowatt.

The loss of energy in the batteries may be taken at about one-third, but the energy put into them would all be generated at times when the station is not fully loaded, and would involve very little, if any, additional labour at the central station. The saving in labour per unit generated would more than cover the losses in the batteries.

The following comparison depends only on the relative amounts to cover interest on capital, maintenance, and depreciation.

Additional central-station plant and feeders, costing £100 per kilowatt, involves an annual cost of £9·6 per kilowatt per annum.

A battery sub-station costing £70 per kilowatt involves an annual cost of £11·3 per kilowatt per annum, including the high rate of 15 per cent. for depreciation on the storage cells.

These figures show that although the batteries save 30 per cent. in capital, the heavy cost of maintenance overbalances that advantage.

In a few years' time, however, the comparison will be different, as improvements are being made which tend to make batteries cheaper and more durable. It is practically certain that the cost will be reduced below £60 per kilowatt, and the maintenance below 10 per cent., thus reducing the annual cost to less than £7·8 per kilowatt, or considerably less than the cost with additional central-station plant and feeders.

The corresponding figure in the case of the alternating-current system, with feeders about one mile long, would be about £9 per kilowatt per annum.

The saving in labour per unit produced at the central station, due to working the machinery at a good load during the day to charge batteries, tells largely in favour of using battery sub-stations. In the case of residential districts, where the producing capacity of a station may be trebled by the addition of battery sub-stations, the £7·8 per kilowatt will be much reduced.

Some battery makers already contend that the cost of maintenance is less than 10 per cent., but even if this is conceded, it still remains better policy to defer for a few years spending large sums on batteries, to increase the capacity of works, in order to take advantage of improvements which are sure to be made. There is no prospect of corresponding improvements in central-station generating plant.

Central-station plant lies idle for very long periods of time. The output during the year under ordinary conditions at the present time only amounts to about one-tenth of what it might be if the machinery ran continuously at full load, and even in foggy days in winter in business districts the output never reaches the equivalent of 12 hours' run at full load. In residential districts the maximum output in any one day probably never reaches the equivalent of 8 hours' run at full load. It follows, therefore, that central-station plant could be made to generate two or three times as much electricity if storage batteries were provided at sub-stations. This affords a convenient mode of doubling or trebling the capacity of continuous-current stations in the future without incurring any expenditure at the outset to facilitate extensions later on. The battery stations can be erected in any positions where the demand requires fresh provision to be made, and can be connected to the distributing mains from which the storage cells would be charged during periods of light load.

Rate of Interest on Capital.

In the comparisons given, the rate of interest upon capital has been taken at 5 per cent. in every case. If other rates were taken the results would be slightly different.

Most Local Authorities can borrow money at 3½ per cent., and at this low rate of interest the difference in comparative annual cost tells slightly in favour of the system which involves the largest capital outlay. In the case of a company seeking 10 per cent. dividends, the comparative annual costs must be modified slightly in favour of the system which requires the smallest capital outlay.

The cost of working an installation by a Local Authority is often compared with that under a company, without bearing in mind that the authority is paying off its capital while the company is not. A Local Authority can pay off its capital in 25 years with 3½ per cent. interest, in annual instalments amounting to only 6·06 per cent. on the capital, or in 42 years in instalments of 4·6 per cent. on the capital.

MR. DENNY LANE ON ELECTRIC LIGHTING.

At the Thirtieth Annual Meeting of the Incorporated Gas Institute, at Belfast, on Tuesday, Mr. Denny Lane, M.A. (the President), after some preliminary remarks, said :—

Within the now waning century, three great developments have taken place—all, from their magnitude, necessarily co-operative—gas, railroads, electricity. I am not old enough to have stood by the cradle of the first; but I have travelled on the first passenger railways in England, France, and Belgium, when I believe no others were open in the world. I saw the telegraph at work when it was open only from Paddington to Slough. I saw the earliest glow lamps, and heard some of the earliest telephones. "Once upon a time there was a king, and he had three sons," so begin scores of fairy tales; and gas, the iron-way, and electricity are the three "princes of the blood" whom the nineteenth century has engendered. I need not tell you that the eldest was and is, according to the story-tellers, the worst of characters; the second middling; and the youngest a paragon of all the virtues. Passing over the second prince, whose mediocrity condemns him to oblivion, let us study a little the characters of the vicious heir, gas, and the virtuous *frère cadet* of this royal house, entitled electric light. If the views I present seem too elementary to some of you, I have only to say that I do not seek to teach those who know everything already, but rather to give a general view of the subject to such of you as have not had time to see both sides of the shield.

It may be thought that I cherish some prejudice against electric lighting. On the contrary, I have a most friendly feeling towards that mode of illumination; for since its advent the manufacture in which we are most interested has progressed more rapidly than at any former period. The Company with which I am connected have more than once proposed to the Local Authority to take powers to supply the electric light; but the Corporation has dissented. When properly managed, I believe the light is beautiful and convenient for those who can afford to pay for it; but no better evidence of its costliness can be found than that the West End clubs of London—the richest and most luxurious institutions in the world—signed not long since a "round robin," complaining of its high price. So far as we are concerned, the new light, instead of being a star of ill-omen, has been the harbinger of success.

The figures I employ have been taken from those given by the electricians themselves. I wish that they would reciprocate this fairness, and, adopting our statements, imitate the "sweet reasonableness" which we proffer to them, and avoid the utterly unfounded statements about gas and its evil behaviour, especially its

Digitized by Google

deleterious effects upon health. I may give one case from my own experience. About fifty years ago a professional friend of mine had gas introduced into every room of his house. Ten children were born there—the population running somtimes up to sixteen persons. But no death took place except one—that of a lady no longer young; and it was never alleged that she was poisoned by gas. The disciples of Malthus should therefore wreck all the gas-works they could reach, if this were generally the case.

The mis-statements of some of the advocates of the new light are ludicrous. Several of them assume that we manufacture nothing but gas, and "remember to forget" that the raw material yields—in coke, tar, and ammonia—products which often pay 75 and sometimes 100 per cent. of the prime cost of the coal. Again, they measure the light given by defective burners; but they allow no credit for good ones. If gas be burned in a Bunsen burner, I can show that London gas does not reach a 1-candle standard; and most bad burners are modified Bunsens, in which air is unduly mixed with gas. Again, they assume that an incandescent lamp retains its original power; while it has been proved that a 16-candle lamp declines to 8 candles, and averages only 12 candles. The Board of Trade was over liberal to the new agent, when it allowed 10 units to be the equivalent of 1,000 cubic feet of gas. Practical men say 12 or 13 units would be more correct; and yet these one-sided advocates put down only 6 units as the equivalent.

In a recent Paper, on the "Economy of Electric Lighting," that eminent electrician, Mr. Gisbert Kapp, has pointed out that, when glow-lamps are used at the power marked by the makers it takes $4\frac{1}{2}$ watts to give 1 candle. Indeed, the electricians themselves calculate that the 8-candle lamp requires 35 watts when new, or $4\frac{3}{8}$ watts per nominal candle—a quantity largely increased as the lamps grow older. Now London gas gives per 1,000 cubic feet 3,300 candles, which, multiplied by $4\frac{1}{3}$ watts, gives 14,300 watts, or over 14 units, without counting cost of lamp renewals, or the serious falling off in light-giving power. Allowing a small sum for the latter item, we may say 15 units are the equivalent of 1,000 cubic feet of gas; and at 8d. 15 units cost 10s., as against 2s. 9d. or 3s. When cannel gas is supplied, the contrast would be still more striking—over 20 units to 1,000 cubic feet. Mr. Kapp proposes to overwork the glow-lamps, giving them a shorter life; believing that the extra cost of renewals will be more than compensated by the saving in current. These wilfully blind advocates shut their eyes to the fact that a gas burner may be checked in consumption, while the new lamp must be left full on or quite off—"Hobson's choice; this or none" From counting 16-candle they have come down to 8-candle lamps; and in other small ways they have endeavourced to "whittle down" the comparative cost of the current. These statements often come from men whose names were never heard of in connection with electricity; and the authors of them might be pardoned on the theological ground of "invincible ignorance."

But, amongst them all, the boldest in reckless assertion is one who cannot plead such an excuse—Mr. Preece, the Electrician to the Post Office—a public official receiving a public salary as head of the Telegraphic Department. He has become the adviser of corporations and private companies, and the competitor of independent engineers who are not paid from the public purse. I will give you one example of his dignified style, taken from his inaugural address delivered to the Institution of Electrical Engineers last January. He says:—"If a full load could be maintained during the whole 24 hours, electrical energy could be manufactured for one-third of a penny per supply unit, which is equivalent to gas at 2d. per 1,000 cubic feet. The potentiality of economy in electric lighting is thus beyond the dreams of the *gasmen*. The most marked features in the development of this great industry are the ostrich-like blindness of the gas manager, who buries his foresight in his fat dividend, and the childish wailings of the gas technical journalists. The gas industry should itself have nursed the herculean infant who is rapidly strangling its main sources of profit." As one-third of a penny per unit is under a farthing per horse-power, I can promise Mr. Preece to maintain his full load during the 24 hours when he is prepared to supply power at that rate.

"Save me from the evil spirit," exclaimed Paul Louis Courier, "and from *metaphors*!" Here, in a small segment of a short paragraph, you appear, gentlemen, as "dreamers," as "ostriches," as "puling babies," and as the "snakes" that the infant Hercules strangled in his cradle. But not only are these threadbare metaphors mixed one with t'other, but you are combined with the most ungracious language. You can determine how far it is consistent with the dignity of a gentleman, the culture of a scholar, or the *esprit de corps* of an engineer, to employ towards those whom he should regard as members of a kindred profession, terms which, if meant for wit, are devoid of humour, and, if intended as contemptuous, recoil on him who fell low enough to use them. The dignified periods of Samuel Johnson are combined with vulgarity; and if hereafter his dignified and potent shade will meet that of the Mercury of the English Post Office in Elysium, it will no longer be Elysium for the latter.

Mr. Preece proceeds to say that the "electric light is essentially the poor man's lamp," although I have already told you that in the district most densely-packed with palatial hotels and luxurious clubs, which use the light for the longest hours, this poor man's lamp has been found too expensive for the very capital of club-land.

I will, with your permission, give some specimens of "the potentiality of wealth beyond the dreams of avarice," which Mr. Preece promises to those who embark with him on his voyage to El Dorado.

I will merely mention, in passing, the London Electric Supply Corporation; but it would be unjust to reasonable electricians to compare their schemes with that of Mr. Ferranti. By Mr. Field's tables the income of the three London Gas Companies is £4,724,000, while the capital is only £15,144,000, or three and a-half times their annual revenue. The gas capital employed by eight large cities supplied by corporations is £8,015,000, or a little over four times their income of £1,978,000. Ten large provincial companies receive annually £1,725,000, while their capital is only £5,756,000, or three and a-quarter times their revenue. The London Electric Supply Corporation in 1892 had an income of £24,282, with a capital of £836,000—equal to 34 years' revenue. This income, instead of increasing, was £4 400 less than that of 1891; and the expenditure exceeded it by £3,914, leaving a loss of this amount. Of the current generated, 58 per cent. was wasted in mains and transformers, leaving only 42 per cent. at the consumers' meters. But the distribution is now to be amended under the skilful guidance of Dr. Fleming; and the Directors hope that the "unaccounted for" current will be reduced to 30 instead of 58 per cent. But even this reduced amount looks formidable enough to the eyes of a gas engineer. As a specimen of waste, I may mention that the outlay on instruments alone (exclusive of meters and transformers) was £12,000—not far from a half-year's income—which would be much the same as if the Chartered Company were to spend £1,500,000 on pressure-gauges, governors, photometers, &c. I think I may promise for Mr. Methven that he will not advise such an outlay.

I sincerely regret the evil fortune that has attended this great experiment, which seems to have been dogged by ill-luck from the commencement; but even under the most favourable circumstances, success could not be expected for a design planned on such extravagant lines. It may have been "magnificent," like the Balaclava charge, but it was not a serious campaign. Mr. Ferranti—the general who set the squadrons in array—seems to have exercised a spell-like witchcraft over the first Board of Directors. Now, under the financial management of Mr. Staats Forbes, I trust the affairs of the Company may improve, especially as at Deptford he is seconded by Mr. D'Alton, an able practical engineer, who has already introduced valuable improvements, and has, moreover, the crowning virtue of being an *Irishman*, of a lineage which, to judge by my own experience, will not be without its value in your eyes.

But dismissing, for the present, this case of wild extravagance, let us see what the average result of such investments has been. That Cyclopædia of Science called the "Electrical Trades' Directory for 1893," so admirably brought out by the publishers of *The Electrician*, is the latest authority I can refer to; but, as the campaign of 1892 was not closed when it was compiled, I must take the profits of the year 1891. From October, 1878 to 1882, 56 companies were floated, with a total capital of nearly 21 millions. More than half of this was paid up, and nearly all has been lost. At the close of 1892 the electric light companies of the metropolis had a capital of £5,250,000, of which £2,700,000 had been paid up. The total profit for 1891 was £25,000, or less than 1 per cent. At the same time, the electric manufacturing companies had a capital of £4,750,000, of which £2,700,000 had been called up, and earned a profit of £211,000, or nearly 8 per cent.—a fair, but still moderate, profit on a fluctuating business. I have excluded the Edison-Swan Company, who only make lamps, and the Woodhouse and Rawson Company, which declared a dividend of 15 per cent., and were practically bankrupt the year after.

I will give an example of a town where gas and electricity have been in competition for over ten years—Eastbourne—which has, therefore, the benefit of accumulated experience—an experience so valuable that the officials of the Electric Company wish to keep it all to themselves, for they have refused to give a copy of their balance-sheet to a ratepayer who had contributed his quota to the public lamps which they supplied. This was a foolish attempt to conceal what could not be hidden. The total capital of the Company amounts to £37,000, of which only £400 is preference, on which, I believe, a dividend has been paid for some time: but this year the ordinary shareholders have for the first time been accorded a dividend. Charging 9d. per unit, the balance of profit and loss is £431, of which £233 is brought forward from a previous account, leaving the annual profit £198. But £169 of this arose from the sale of fittings, and £25 was received for a pupil's fee. If these two sums be deducted, we find the profit on electric lighting amounts to £4, for earning which the Directors justly received

Digitized by Google

£250—too small a remuneration, when we consider the anxiety of mind caused by trying to navigate a craft so unseaworthy amidst shoals and breakers. They are now calling for more capital to be invested in this mine of gold, "this potentiality of wealth beyond the dreams of avarice," as Mr. Preece calls this "great industry." Why do the Directors not ask him to devote some of the abundant leisure which he has to spare from his official duties, and by his divining-rod find this hidden vein of gold into which they have not yet sunk a shaft? In this same town of Eastbourne, when the electric light was started in 1882, the consumption of gas was 90,584,000 cubic feet; in 1887, 146,068,000 cubic feet; and in 1892, 207,036,000 cubic feet—an increase of 107,452,000 cubic feet, or over 107 per cent. Thus was this "spotted snake" strangled by the "Herculean infant." An old Cork rhyme runs thus :—

It is better to fall with your back in a set of furze
Than venture to play with those ticklish things, *metaphors*—

rhyme *and* reason which I commend to Mr. Preece. I may remark that this engineer has recommended the Corporation of Bristol to charge 6d. per unit, being 1,800 per cent. over what he says electricity could be supplied at "if the load factor was uniform."

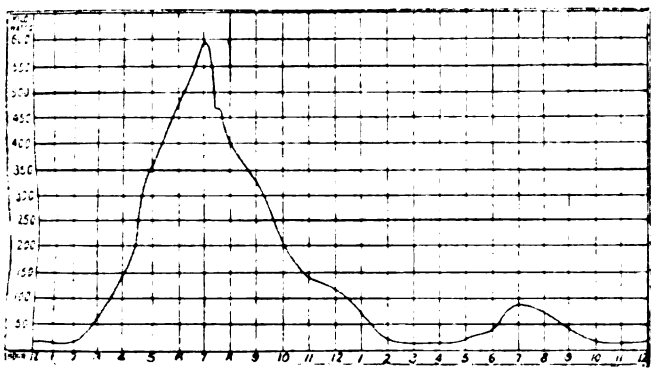

Diagram Showing Electricity Supplied from a Central Station in Midwinter.

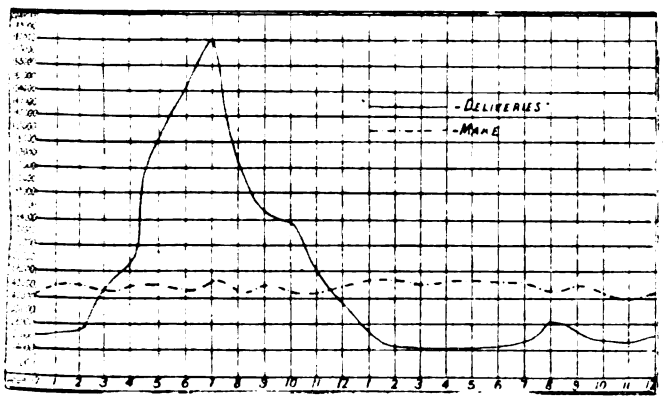

Gas made in 24 hours, 1,174,000 cubic feet.
,, delivered, 1,263,300 cubic feet.

Diagram Showing Make and Deliveries of Gas from the Cork Gas-Works on December 23, 1892.

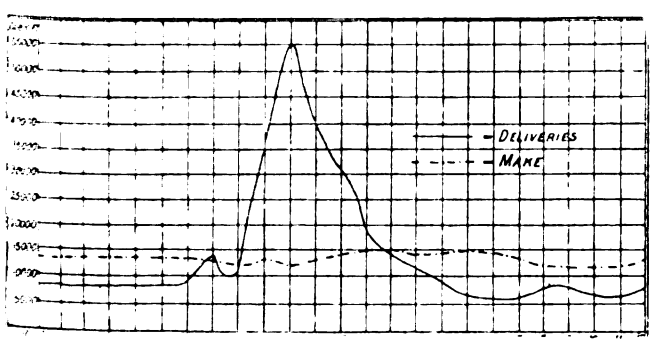

Diagram Showing Make and Deliveries of Gas from the Cork Gas-Works on June 22, 1892.

It is, I think, Mr. Crompton who first invented the very useful term *load factor*, meaning the ratio between the average and the maximum delivery of electricity. Of course, gas engineers have a load factor of a somewhat similar kind, but their system of storage enables them to put by the surplus of the day production to help the hours of darkness. With the alternating current, no storage is possible; and hence, if the dynamo ceases to work for even a few seconds, all lights are extinguished. With the continuous system, accumulators afford a partial but a very expensive and wasteful remedy. If we put 100,000ft. of gas into a holder, and got only 85,000 out, we should say things were going on very badly. Yet this very bad result is the very best claimed for storage cells, and in some cases the loss, I believe, is 40 per cent. The lot of the gas manager is also made more easy by the fact that a large percentage of gas is used by day for heating, cooking, motive power, and manufacturing purposes, thus filling up, to some extent, the deep hollow of the electric diagram. The sudden rise and the sudden fall of the curve produce the greatest difficulty which meets any system unprovided with storage power; indeed, some of the statements under this head are startling. Prof. Unwin states that within the 24 hours the demand varied from four times the mean to one-twentieth of the same quantity; that is to say, that the maximum was 80 times more than the minimum output. Even in gas distribution the maximum is 50 times as much as the minimum hour.

The latest authority is Prof. Ayrton, who, in his monograph prepared for the British Electrical Section of the Chicago Exhibition, states that the average hours of consumption of the electric light in private houses is only 1 hour in the 24, in shops and flats only 1½, and that it is only clubs and theatres that exceed this limit. Let us see the result that this leads to. He says that the whole of the electric lights fixed in Great Britain are equal to 750,000 8-candle lamps. Allowing even 800,000 lamps, this would be equal to 400,000 16-candle lamps, and, allow even 1½ hour, would mean 600,000 lamp hours, which could be supplied by 600,000 × 5 = 3,000,000ft. of gas a day, or equal to 1,100 million feet of gas in the year. This is less than the Brentford Gas Company sells. The town of Nottingham consumes more, and the combined consumption of Plymouth and Portsea is considerably more. The total sales of gas in London are 30,000 million cubic feet. The annual increase lately has been about 6 per cent., or 1,800 millions, so that the increase of gas consumption in London alone in one year would give one and a-half as much light as the whole electric lamps of Great Britain.

If we were situated near the Equator, the variation of the days would not be so great; and if we worked at night and slept by day the load factor would be much more convenient for us all. Or if we lived near the North Pole, we might work our dynamos for half the year, and let them sleep beneath the midnight sun for the other half. But placed as we are, where the seasons' change is so wide, this load factor becomes a burthen indeed. Make the case your own. Suppose that you had no gas storage, then in the lightest hour you should have as many retorts heated as may be required for the supply of the heaviest possible demand; for it is the *maximum hour's* consumption you should be prepared for, and in many cases the electrician has practically to provide, not for the maximum hour's, but for the maximum minute's output.

I have said that, besides the great aid that you derive from storage, your load factor is greatly alleviated, and your feelings soothed, by the fact that every year the "day" consumption of gas for heating, cooking, power, and other manufacturing purposes increases, while the lot of our younger rival is not yet made happy by such consolatory aids. Mr. Methven, in his recent interesting address, has shown that in the district of the Chartered Company the consumption of gas from 6 a.m. to 6 p.m. has been 37 per cent. of the total; and in other London districts a little under 30 per cent. Of course, we have heard of electric cooking, and I have seen the amusing experiments on this subject; but this and electric heating are reserved for that happy class "who have more money than they know what to do with."

Mr. J. Ferguson Bell, of Stafford, gives the following as the respective costs of one million heat-units :—

Gas at 2s. 3d.	40d.
Electricity at 4½d. per unit	1,301d.

The latter being 32 times as dear as heat produced by gas. Electric motors for very small powers will, I expect, come into use; but for anything above ¼ or 1 H.P. it is not likely that people will pay a price so much higher than gas power costs. On this subject I again refer to the authority of Mr. Bell, who gives the following figures :—

Cost of gas power at 2s. 3d. = 0·675d., say, ⅔d. per H.P.
,, electricity ,, 4½d. = 4 500d. per H.P., or, say, 6⅔ times the price of gas power.

Let us now examine what modes have been proposed to get over this difficulty; and, at the outset, it is as well to say that no plan has ever been devised to store electricity itself. The garnering up of other forces forms the only mode of meeting the difficulty of the fat kine and the lean kine—of the brief harvest and the long winter. These forces have afterwards to be transformed into electricity.

First—to begin with the storage cell—no electricity is stored there. It is chemical energy which is laid up. If I take a piece of carbon and a piece of zinc, connected by a good conductor, and place them in an acid, well-conducting and easily-decomposed liquid, the zinc will first be oxidised; and the oxide so formed, combining with the acid, will form a soluble salt. When the zinc has all been dissolved, I place a second carbon in the solution, and send through it a current of a strength sufficient to decompose the salt, when the metallic zinc will abandon the acid and be deposited on one of the carbons, leaving the free acid in solution. We have, therefore, what we began with—zinc, carbon, and an acid solution; and, connecting the zinc and carbon as at first, we begin the series again, and repeat it as often as we like, the zinc being alternately oxidised and deoxidised. This is precisely what occurs in the so-called storage battery. The lead compounds are alternately deoxidised and again oxidised, thus alternately absorbing and envolving a current. In both the cases referred to the oxidation of the metal produces a current, and then an independent current produces deoxidation. As far as I can recollect, Sir William Grove, to whom science owes so much, was the inventor of the first storage system, which he called a "gas battery." A current was passed through two platinum plates and decomposed water—in fact, deoxidised hydrogen—the hydrogen and oxygen being collected in separate tubes. The battery wires were then removed and the two platinum plates connected by a wire passing through a galvanometer, when a current was observed to be produced by the reoxidation of the hydrogen and the reconversion of the gases into water. Gaston Planté discovered that, by alternate oxidation and deoxidation of plain lead plates, similar effects were produced. Then came the innumerable forms of the Faure-Sellon process, in which the lead plates were "pasted" with oxides of lead already formed. Yet I believe that, taking into account durability, no system has yet been invented better than the original Planté process, still surviving in the Howell-Crompton and other systems of accumulators. I have said so much in order to show clearly that in these cells there is no storage of electricity. Indeed, it would be wonderful if any prison could be designed to confine a spirit, not "airy" but far more subtle—in face, "ethereal." As electricity has even disdained the chain of a definition, it does not seem likely that it will be "cabined, cribbed, confined" in any material cell. It passes the wit of man to devise the cunning cage that could confine such a wild bird. These storage cells are undoubtedly often of great use in supplying a small output during the hours of lowest consumption, leaving engines and dynamos at rest for many hours. They are also of use during the hours of heaviest duty, and particularly in steadying the current when the dynamos are running. They are, however, enormously expensive, and occupy a very large space; and I believe there have been explosions caused by the hydrogen evolved. Mr. Kapp, in his lecture at the Society of Arts, puts down their prime cost at £40 to £50 per kilowatt; and as 1,000 cubic feet of gas are equal to 30 kilowatts, we have thus £1,200 to £1,500 for storage, as against £12. 10s. for gas. Mr. Kapp referred to comparatively small plants; and, I believe, for large central stations the capital would be less. But even if it were reduced to half, the cost of electric storage would be still 50 to 60 times as dear as gas storage. In addition, the depreciation is very heavy, and, with wear and tear, maintenance and interest, would sum up to 15 or 20 per cent. Their disadvantages are fourfold:—

(1) Heavy outlay on capital.
(2) Very large space occupied.
(3) Heavy cost of maintenance.
(4) Loss of current, which, in the most favourable circumstances, amounts to 15, and is often over 40 per cent.

They can never be used economically, except as auxiliaries—a kind of very heavy dragoons, to guard the flanks of the main column.

Two other modes of storage have been recommended by very eminent professors; and nothing can more clearly emphasise the difficulty to be encountered than the fact that systems so complex, so expensive in construction, and so wasteful, should be even thought of.

Prof. Forbes, having to deal with the case of Edinburgh—a place possessing for such a system natural advantages such as no other city in the British Islands enjoys—proposes to pump water for all the 24 hours, if necessary, to a reservoir situated at a great elevation, thus storing the potential energy of the elevated water. The water so stored is to actuate during the lighting hours turbines driving dynamos to produce the current. The natural advantage which Edinburgh possesses is this—that within 1½ miles of the city, it has, on Arthur's Seat, a natural reservoir at an elevation of 800ft., and the capacity of this reservoir can be extended. As it exists at present, this reservoir can hold sufficient water to supply 1,000 H.P. for two hours.

For motive purposes, the efficiency of a reservoir is the product of two factors—vertical height and capacity—the number of foot-pounds got by multiplying the elevation in feet by the number of pounds of water stored. Some strange mistakes have been made on this subject, and owners of water-power have imagined that they have had what they called "a fine ponding power," when it really has been of very small amount. A good many years ago I devised the following very convenient formula, which some of my friends have associated with my name. In it I have assumed that the efficiency of the water motor is 75 per cent., a very fair allowance when losses by friction, part-gate, &c., are taken into account. The formula is this: "One acre of water, one foot deep, gives one horse-power for one hour for (each) one foot of fall."

This tells us at a glance how large the impounding reservoir must be unless the elevation be very great. Prof. Forbes has, therefore, at Edinburgh, the unusual good chance of a ready-made reservoir at a very great elevation, and very near the city. Yet, under these circumstances, let us see what the losses may be, independently of the fuel used by the engine which drives the pumps.

First, the efficiency of the pumps themselves (including leakage of valves) cannot, I suppose, be higher than 85 per cent.; friction of rising main, which, being continuously at work, may be of smaller dimensions than the falling main, may cause a loss of 10 per cent.; for delivery main, say the same; efficiency of turbine, 75 per cent. Of course, I do not take account of efficiency of dynamo, which would be the same as if it were driven directly by steam-engine. The ultimate efficiency would, therefore, be $0{\cdot}85 \times 0{\cdot}90 \times 0{\cdot}90 \times 0{\cdot}75 = 51$ per cent. We should also count for interest and depreciation, say, 15 per cent. on the pumps and turbines, and 6 per cent. on the mains, and 5 per cent. on any outlay required for the extension of the impounding reservoir, besides rent and cost of "way-leave."

Against this the economies would be the cost of smaller steam-engines (worked, however, for longer hours), and the saving of fuel lost in getting up and letting down steam. We have also to look to the additional contingencies which arise under this system. The bursting of a main, the break-down of the pumps, the sticking of a valve, the choking of the turbines—any one of these events would stop the supply of light. Even in the very favourable position of Edinburgh, I cannot see that this system commends itself to engineers.

(To be continued.)

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *June* 2, 1893.

The Late Prof. Moses G. Farmer.—Prof. Moses G. Farmer, whose death at the age of 73 occurred in Chicago on May 25th, was one of the earliest pioneers in the electrical field in this country, and was one of the best-known American electricians. After his graduation from Dartmouth College, in 1844, he exhibited an electro-magnetic engine of his own invention for the miniature railroad in connection with a lecture on electro-magnetism, and at the same time illustrated the application of the electric current to the explosion of torpedoes and submarine blasting. For a number of years he devoted his attention to telegraphic work, perfecting a fire-alarm system, and devising a system of multiplex telegraphy, and the printing telegraph, operated by an electro-magnetic motor. He lighted his own house in Salem by electricity in 1859, and it was said to have been the first house thus illuminated. During 1865-6 he invented what is known as compound wire, that is, wire having an iron or steel core with a copper cover. Later he made many important improvements in dynamo-electric machines, one form of which is the well-known Wallace-Farmer machine, and another form which is still used for torpedo work in the Navy. In 1872, he accepted the position of electrician at the United States Navy Station at Newport (R.I.), where he remained until 1881, when he was obliged to retire on account of ill-health.

The Tesla Lecture.—The publication of the lecture delivered by Mr. Nikola Tesla before the Franklin Institute, and later before the National Electric Light Association, at St. Louis, has been awaited with the greatest interest in this country, not only by fellow workers in the same or similar fields, but by electricians in general, and by the great mass of the electrical public, who would naturally not be expected to manifest any special interest in such work.

The General Electric Company.—The publisher of *Electricity* has been indicted for criminal libel by the General Electric Company.

CORRESPONDENCE.

THE PUPIL SYSTEM.—A SUGGESTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The pupil controversy, which was recently raging, or, more accurately, sauntering along, in some of the papers has apparently died a natural death. I should like to suggest that firms, taking in (in the common sense of the phrase) a large number of pupils, should devote the premium of one of them, say £100 a year, to a skilled workman, whose duty would be similar to that of a workshop instructor in any of our technical schools, *i.e.*, he would go the rounds of the pupils every day, and explain anything in the way of fitting or the use of tools on which they might be engaged, and would be accessible to them at any time when they should happen to be in difficulties.

This would be an advantage to both foreman and pupil, for whilst the former's chief complaint against the latter is that he is constantly stopping the men's work to ask them questions and get assistance, the latter soon discovers that information can only be obtained by considerable coaxing and promises of "drinks," which sometimes mount up to an alarming total.

I cannot see that there would be any difficulty in obtaining the services of an "instructor," as there are men in all works who add to their incomes by performing these duties unofficially. From whatever point of view it is looked at, it seems to be a better plan than the present one, or rather, the absence of plan which at present exists for imparting knowledge to the pupil, who, I venture to think, has a right to expect some such assistance in return for his premium.

It is to be hoped that some firm will try the experiment, which cannot do any serious harm, and the pros and cons will be brought to light more fully than they possibly could be by any amount of ink-slinging.—Yours, &c.,

June 14, 1893. DISCIPULUS.

THE PRICE OF ELECTRIC SUPPLY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In a leaderette in your issue of 9th inst. you refer to the fact that none of the systems of charging at present adopted by electric supply companies tend to encourage a day load—that is, of course, excepting the St. Pancras plan.

It seems to me that the day load is (for continuous currents) to be looked for in a large extension of the use of accumulators close to the lamps they are to light. With accumulators at present prices, the arrangement is feasible, as shown by the figures below; while improvements and reductions in price will still further facilitate matters.

We may take it, I think, that a supply company could now contract for a number of accumulators at the price of £2 per 16 c.p. lamp, to be supplied for, say, five hours, and in a large number of buildings to be lighted there would be no difficulty in finding a cellar or out-house that could be used as a battery-room. The batteries might be provided and looked after by the supply company, the consumer paying a reduced charge for current and a rent to cover interest and maintenance expenses, or simply getting a small reduction in price if he allows the battery to be placed on his premises. It would, of course, be advisable that the batteries should be charged by a special system of mains, which, owing to the long time allowable for charging, need be of only small size, and would be connected to the charging dynamos only during convenient hours. The house-circuits would be supplied through automatic variable resistances, or would be controlled by automatic switches, which would keep the pressure at the lamps constant. The batteries being all in parallel, any consumer requiring an extraordinary amount of lighting would be partly supplied from his neighbour's stores; but, as the meters would be fixed on the separate house circuits, this would harm nobody. Where circumstance suited, of course one battery might be arranged to supply a group of houses. Now, consider the question of cost. We will assume that the charging current can be supplied during the day at such a price that the energy taken from the batteries will be charged for at half the rate for lamps run directly from the mains, and that the charge per 16 c.p. lamp per annum comes out at 10s. and 20s. respectively. Taking the case of a building containing 50 lamps, not more than 40 of which are, excepting under quite abnormal circumstances, lighted at once, we have:—

Cost of accumulator to run 40 lamps for five hours, £80; annual interest at 5 per cent., £4; annual renewals at 7½ per cent., £6; making the annual cost to consumer:

Without accumulator, 40 lamps at 20s.				£40	0	0
With accumulator, 40 at 10s.	£20	0	0			
Interest	4	0	0			
Renewals	6	0	0			
				30	0	0
Annual saving by use of accumulator (=25 per cent.)				£10	0	0

If, instead of having the batteries always in connection with the charging mains, it was arranged that each house had to disconnect from the mains before any lamps could be lighted, the charging might be done at, say, 300 or 400 volts, and a corresponding saving in the cost of mains would result. Of course, if each house had to rely solely on its own battery, this would have tobe somewhat larger than if others could be drawn upon occasionally.

As regards the estimated charge for day current, if the St. Pancras Vestry can afford to supply motors at half price between fixed hours, a further small reduction could certainly be made if the supply was to be given only at convenient times.—Yours, &c., W. S. BOULT.

60, Castle-street, Liverpool, June 13, 1893.

AUTOMATIC TRANSFORMER SWITCH.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to your brief notice of our "Automatic Transformer Switch" in the current number of your paper, we should like to point out to your numerous readers that the impression conveyed therein is rather misleading in certain details, and requires the few following explanations:—Firstly, the trains of clockwork are delicate relay mechanisms, which are automatically re-set by the action of the switch, and *do not require any attention*. Secondly, there is only one moving contact and one resistance switch (which is rendered sparkless by three small coils), in addition to the primary and secondary switches. Thirdly, the true action of the apparatus is as follows:—When first the primary and secondary circuits are completed, sufficient energy is stored up (from the secondary) in a few moments to "switch off" *and* to "switch on" again; switching off the last light releases a portion of this stored energy, and switching on a light again releases the second portion of energy.

It is further proposed to replace the weak primary battery by a condenser or high resistance across the primary switch terminals. Where transformers are fixed in each house in combination with this switch, a saving of at least 8 per cent. on the total electrical horse-power generated at the station would be effected.—Yours, &c., NEW AND MAYNE.

Palace Chambers, 9, Bridge-street,
Westminster, S.W., June 12, 1893.

LEGAL INTELLIGENCE.

White v. Tussaud.

The defendant in this action applied on Wednesday last to the Court of Appeal for a new trial, alleging misdirection.

The case was originally heard on April 24th last, and resulted in a verdict for the plaintiff, Mr. T. M. White, an electric light contractor, who originally claimed £762. 16s., balance of an account of £1,072. 16s. for fitting up for the electric light a waxwork gallery for Mr. Louis Tussaud. There was a charge of £699 for installing 466 lights, and for extra work done an additional sum of £373. 16s. was claimed. Defendant had paid £310. The contract was entered into in November, 1890, but in April, 1891, a fresh contract was made to include the work already done, and also further work for which an order was given. In the month of June following a fire broke out at the gallery and prevented the carrying out of the contract. Defendant contested the claim upon several grounds, alleging that it was never agreed that 30s. per lamp should be charged, that the work under the first contract was never carried out, and that such work as was done was very badly done. The jury in the action found that the work contemplated by the first contract was duly performed, and gave a verdict for the plaintiff for £583 and costs.

Digitized by Google

the difference between that sum and the amount of the claim being on account of deductions for lamps supplied, but taken back again by the request of the defendant.

Counsel having argued the case on Wednesday and Thursday, the Court dismissed the appeal with costs.

The MASTER OF THE ROLLS said if nothing had happened to take away plaintiff's rights under the first contract, and if he did all the work which that contract obliged him to do, then he must be paid for the work which he did according to the terms of that contract. There was distinct evidence that the work was done, that the 466 lights were put in, and the extra work in connection with them carried out. But there was a new contract made between the parties, and the question was, Did the existence of that new contract under the circumstances do away with the plaintiff's rights under the first contract? In his view, where there was a pending contract, and a second contract was made after the fulfilment of the first in respect of the same subject-matter, *primâ facie* the second was not taken at that moment as satisfaction of the first, but was only taken as satisfaction of the first when the second was completed. As a matter of evidence it lay upon those who asserted that the second was taken at the moment it was agreed to as satisfaction of the first to prove it; it was so contrary to all ordinary views of business. And unless they proved it clearly, it would always be held by all courts and all juries that the making of the second contract was not taken as satisfaction of the first. It seemed to him that the learned Judge made clear to the jury the question they were to try, and they found a verdict which could not be set aside. Therefore the appeal must be dismissed with costs, and the verdict and judgment must stand.

Verdict accordingly.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

TENDERS INVITED.—The Midland Railway Company invite tenders for the erection of buildings for their electric light machinery at Sandon Dock, Liverpool. These tenders have to be sent in to the Secretary of the Ways and Works Committee, Derby.

——— The Greek Government are inviting tenders for the necessary telephonic apparatus required for from 200 to 300 subscribers in Athens and the Piræus. The Telegraph Department will furnish the necessary posts, and all other materials may be imported by the contractor duty free. The work is to be carried out under the supervision of a State Committee, whose decision in all matters in connection with the tender will be final.

——— The Highland Railway Company invite tenders for various stores, including telegraph instruments, fittings, telegraph construction material, galvanised wire, lamps, lubricating oils, iron castings, &c., &c. Tenders must be lodged with the secretary, Mr. And. Dougall, at the Company's offices, Inverness, not later than Saturday, the 24th inst.

——— Tenders are required for lighting the Victoria Pier, South Shore, Blackpool, for which plans and specifications can be had of Mr. Harker, 78, King-street, Manchester, on or before the 17th inst.

TENDERS ACCEPTED.—The tender of Messrs. Pritchetts and Gold has been accepted by Messrs. Lambert Bros., for a complete electric lighting installation at their coal hoists at the Galleons, Royal Albert Docks, London, E., for the sum of £625.

——— The Portsmouth Town Council have accepted the tender of Mr. J. R. Penning for keeping in order the electrical apparatus at their pumping station, at £30.

APPOINTMENTS VACANT.—The Electric Lighting Committee of the Borough of Kingston-upon-Hull are prepared to receive applications for the appointment of Resident Electrical Engineer to take charge of their electric lighting station, at a salary of £250 per annum. Some particulars are given in our advertisement columns, and all other information can be obtained of Mr. R. Hill Dawe, town clerk, Kingston-upon-Hull. Applications must be in before noon of Thursday, June 29th.

——— The Vestry of St. Mary, Islington, require an electrical engineer competent to prepare plans and specifications in connection with the installation which the Vestry are about to inaugurate. Some further particulars will be found in our advertisement columns, and applications must be sent in to Mr. Wm. F. Dewey, the Vestry Clerk, Vestry Hall, Upper-street, London, N.

APPOINTMENT.—Mr. George H. Cottam has been appointed electrical engineer to the Hanley Town Council at a salary of £200 per annum. There were sixty-four applicants, ultimately reduced to four, from whom Mr. Cottam was finally selected.

PERSONAL.—We are asked to state that Mr. P. C. Middleton, late manager of Messrs. Walter Andreae and Co., has joined the staff of Messrs. New and Mayne.

MR. ROBERT W. PAUL.—We have to acknowledge the receipt of List No. 5, giving illustrated descriptions of the instruments manufactured by this firm. Descriptive illustrated price lists Nos. 1 to 6 can be obtained on application.

BANKRUPTCY.—A first and final dividend of 11d. in the £, in the estate of James Collins, formerly carrying on business as an electrical engineer at 80, Church-road, Hove, is payable at 7, Pavilion-buildings, Brighton, on the 21st inst.

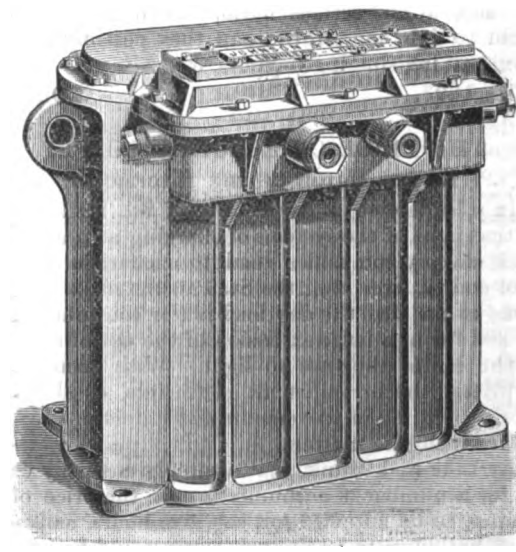
MOUNTAIN'S WIRE MANUFACTURING COMPANY (LIMITED).—The accounts filed under the winding-up proceedings of this Company show total liabilities £6,754, of which £3,042 are expected to rank. The assets, valued at £3,711, are absorbed by the claims of the debenture-holders, and the total deficiency as regards contributories is returned at £18,872. The failure of the Company is attributed by the Directors to bad management and to insufficiency of working capital. Mr. Mountain, however, attributes the failure to excessive working expenses, bad trade, and consequent low prices.

DISSOLUTION OF PARTNERSHIP.—Messrs. Young and Harrison, trading as the Economic Telephone and Electric Supply Company, at 58, North Corridor, Royal Exchange, Manchester, telegraph contractors, have dissolved partnership. Mr. J. R. Young, who continues the business, will pay all debts.

FIRE.—On Sunday morning a serious fire occurred at the generating station of the Morecambe Electric Light and Power Company (Limited), Morecambe, Lancs., by which damage was done to the extent of about £350.

LUBRICATING OILS.—Messrs. W. H. Willcox and Co., of Southwark-street, S.E., have just issued a new price list of their lubricating oils, which can be obtained on application. Accompanying the list are illustrations of the special makes of lubricating oils, lubricators, oil filters, &c., made by the firm.

MESSRS. JOHNSON AND PHILLIPS' TRANSFORMERS.—This type of transformer is the outcome of considerable experimental work,



including the testing of various qualities of iron, and has resulted in a most satisfactory and approved design. The makers inform us that the magnetising-current is very small, and the drop of volts between no load and full load is considerably less than in other transformers. The case is made of cast iron and is perfectly water-tight, glands being provided for both the high and low-tension leading wires. Stock transformers are of the following voltages:—From 2,400 volts to 100 or 50 volts; from 2,000 volts to 100 or 50 volts; and from 1,000 volts to 100 or 50 volts.

MESSRS. NALDER BROTHERS AND CO.—This firm are now making mirrors for galvanometers and other purposes, and have added a department for general optical work.

THE HOOK OF HOLLAND.—The Great Eastern Railway Company have sent us a pamphlet and a guide book of this new route to the Continent. The Hook of Holland is at the mouth of the Maas, and the traveller thus avoids the journey up that river to Rotterdam. The books contain all particulars about the route except the fares and the length of the passage.

THE ROYAL WEDDING.—Among the suggestions for illuminations on the occasion of the Royal Wedding on July 6th, it is proposed that special illuminations of the Mansion House, Tower Bridge, St. Paul's Cathedral, the Bank of England, the Law Courts, Somerset House, and other large public buildings *en route* to Liverpool-street Station should be effected.

TELEPHONE SUBSCRIBERS.—The New Telephone Company send us their latest list of Manchester, Bolton, and Eccles subscribers.

Digitized by Google

TELEPHONIC EXTENSION.—Llandudno and Colwyn Bay are being connected by telephone, and a new Exchange will shortly be opened by the National Company at the Central Chambers, Colwyn Bay.—A trunk line is also to be constructed to Rhyl, and a Central Exchange is to be erected in that town.

WOODHOUSE AND RAWSON UNITED (LIMITED).—The following circular is issued by Mr. T. D. Leslie, the Receiver and Manager:—"Having had numerous inquiries as to whether the business of Woodhouse and Rawson United (Limited) is still being carried on, I beg to inform you that it is, and will be continued, under my personal supervision as Receiver and Manager on behalf of the debentures holders of the Company. I also beg to inform you that, with a view to centralising the business, I am, with the exception of Glasgow, Birmingham, Bradford, Manchester, and Kidsgrove, closing all other branches throughout the United Kingdom. This will enable the head office to keep in direct touch with the numerous customers of the Company and avoid that delay which must necessarily be caused by correspondence between the branches and the head office. The works at Manchester have recently been enlarged by new machinery, &c., having been put down, and I am pleased to say that the Company is now in a position to turn out work thoroughly and promptly."

ABERYSTWITH.—The *Cambrian News* states that if the Corporation would but stand on one side and throw the electric lighting of the town open to competition more than one electric lighting company has expressed its willingness to light the town.

BOLTON.—On a motion to adopt the minutes of the Gas and Lighting Committee of the Town Council, Councillor Tootill complained that he considered unnecessary delay had taken place in the introduction of the electric light, and he considered a great deal of the blame was attachable to the Vice-Chairman of the Gas and Lighting Committee. The Electrical Sub-Committee had, after visiting various parts of the country, sent in their final report; but notwithstanding this, visits had been made to other parts of the country, presumably to obtain further information. He knew of tradesmen who were delaying further expenditure pending the action of the Corporation, and he asked what was the actual position of affairs regarding the introduction of the electric light into the Borough. Councillor Cooper replied that a meeting of the Electrical Sub-Committee is to be held, and a final report would be sent in to the General Committee. It was explained that since the first report of the Sub-Committee was sent in an electrical engineer had been appointed, and it was the opinion of several members of the Committee that he should have an opportunity of seeing several of the electric lighting stations at work in order that he might advise the Committee on the subject. No time would be lost in pushing on with the work so soon as the final report had been approved by the Council. Another member anticipated that some time during the coming winter they would be in a position to supply the electric light.

BRIDGEND.—The Bill confirming the Bridgend Provisional Lighting Order has been before the examiners of the House of Lords, and has passed for second reading.

BRISTOL.—In connection with the Industrial and Fine Arts Exhibition, of which some particulars were given in our last issue, we are informed that it is proposed to make a special exhibit of electroliers, brackets, &c., suitable for the lighting of the Fine Arts Section, free of charge, to firms willing to loan such fittings, the object being that intending consumers of the current, which will shortly be supplied by the Corporation, may have facilities offered them for selecting such fittings as would be likely to meet with their possible requirements. The number of fittings which the Lighting Committee of the Corporation, who had the matter in hand, are able to accept, must necessarily be limited. The Exhibition is to be lighted throughout by electricity from the city mains, and electric work in general is to be made a leading feature. The Exhibition will be opened about the end of August.

CHELSEA.—An exhaustive report by the Surveyor to the Chelsea Vestry, on the lighting of the main roads, has been presented, which the Vestry have ordered to be printed and circulated amongst the members. Reference is made to schemes for the better lighting of the district by electricity. The Vestry, at its last meeting, discussed the advisability of asking the Gas Light and Coke Company to reduce their charge for gas, in accordance with a promise made by the Chairman of that Company to a deputation which waited upon them last year. A deputation was appointed to wait upon the Gas Company.

CLAYBURY ASYLUM.—The new Asylum of the London County Council at Claybury, Essex, will be formally opened to-morrow (Saturday), by Mr. P. M. Martineau, at 3:30 p.m. The building will accommodate 2,000 inmates, and includes workshops for various handicrafts for the male patients. The electric lighting installation is very complete, and consists of 4,500 incandescents. The architect is Mr. G. D. Hine, and the principal contractor is Mr. E. Gabbutt, of Liverpool.

DATCHET (NEAR WINDSOR).—The electric light installation at the Manor House, Datchet, which had been put down under the superintendence of Mr. Farrow, recently appointed Resident Engineer of the Windsor Electric Light Company, is now completed. A Crossley engine drives a Taunton dynamo, and another dynamo is fitted with two fly-wheels to run in parallel with a number of E.P.S. accumulators, which are included in the installation.

DERBY.—An Electrical Exhibition has been opened at the Derby Co-operative Hall, promoted by Messrs. S. Rowbottom and Co., and comprising samples of various makings of lighting plant, apparatus, &c.

DUNDALK.—The Commissioners have resolved to apply to the Board of Trade for a renewal of the Dundalk Electric Lighting Licence.

HALIFAX.—Councillor Braithwaite, at the last meeting of the Borough Council, proposed that such Committees of the Council as used telephonic, telegraphic, or electrical appliances of any kind, be requested to place the repairing, maintenance, alterations, or extensions of such appliances in the hands of the Borough Electrical Engineer, except such as are done by contract. It was pointed out this would necessitate the fitting up of an electrical workshop and other expenditure. After some discussion it was agreed that, attention having been called to the matter, the motion should be withdrawn.

HAMPSTEAD (LONDON, N.W.).—Thirty-one tenders have been received by the Vestry for providing the plant for the proposed electric lighting station in Finchley-road, and nine tenders for the erection of the chimney shaft, and buildings and foundations for the machinery. It was decided, at the last meeting, to advertise again for tenders for the erection of the buildings, and to postpone the opening of the whole of the tenders until the next meeting.

LEYTON.—The Local Board have authorised application to the Board of Trade for a Provisional Order, and the Electric Lighting Committee have under their consideration various estimates in relation thereto.

MOFFAT.—At the meeting of the Town Council, on Tuesday last, Mr. Brown submitted a report by Messrs. Woodhouse and Rawson, Glasgow, with respect to the lighting of the town by electricity. The report stated that by using the water-power obtainable at Skellywell, sufficient power would be obtained to light the streets of the town by 2,000 c.p. arc lamps, and leave to be sold to private persons current estimated to be worth more than £1,900 a-year. The current could be conveyed for the first mile and a-half through the fields by overhead wires, and for the last half-mile by mains. The estimated cost for the works and plant, exclusive of batteries or small accumulating stations required in the distribution to private houses, was stated as likely to be rather less than £3,900. The report is to be discussed at the next meeting of the Council.

MONTROSE.—Some time back the question of lighting this town by electricity engaged the attention of the Police Commissioners, and a Committee now recommend that the services of Mr. Bryson, of Glasgow, be obtained to advise them on the subject. Mr. Bryson agrees to give advice and a full report for £10. 10s.

NEWCASTLE.—At the last meeting of the Lighting Committee of the Council, the subject of the lighting of Grey-street came up for discussion, and it was decided to light this thoroughfare, including Grey's Monument, four lamps to be placed at the Monument and four in Grey-street, each of 1,500 c.p.

NEWPORT (MON.).—The Free Library Committee of the Local Board are discussing what system of electric lighting shall be adopted. The Chairman stated "that the heat caused by the gas was rotting the building."

OSWESTRY.—A meeting of the Town Council is to be held on July 3rd, to consider the application of the local Electric Lighting Company for the Board's sanction to their applying for a Provisional Order. The General Purposes Committee have decided to recommend that the application of the Company be acceded to.

RAMSEY.—The Fire Brigade Committee of the Town Commissioners require an electric fire call, and proposed at the last meeting that a vote for £30 should be granted for this apparently indispensable object. The Commissioners could not see their way to this expenditure until the matter had been further discussed by the Fire Brigade Committee, who are subsequently to report to the Commissioners on the subject.

ROTHERHAM.—At the last meeting of the Town Council the Mayor, in reply to a question as to when the electric lighting subject would be discussed, remarked that, in his opinion, "the question was dying a natural death."

RUGBY.—The installation at Rugby School will consist of about 1,500 incandescents. The generating plant is to be placed, as stated in our last issue, at the rear of the gymnasium, and a special type of gas engine is to be used, with Dowson's gas, which will be

Digitized by Google

made on the spot. The engine is to be 100 H.P., with two impulses to each revolution, with which increased steadiness is anticipated. The lighting is, we understand, to be carried out on the co-operative principle, the house masters finding the necessary capital. It is confidently expected that the cost will be less than the gas and candle lighting now adopted, and that when the students return from the summer holidays in September the light will be in working order.

ST. ALBANS.—The subject of lighting St. Albans by the electric light is being discussed, and the Corporation will be asked to appoint a Committee for the purpose of considering the matter. It is probable the Corporation will decide to apply for a Provisional Order. Councillor Toulmin will propose the Committee, and as he "is not a gas shareholder, has the courage to move in the matter."

ST. PANCRAS.—The Electricity and Public Lighting Committee of the Vestry recently inquired into a temporary depression in the supply of electricity, which occurred on May 8th, the result of their inquiries being that the depression arose from insufficient stoking, the boiler fires having been allowed to get too low, so that when the heavy load of the evening came on, the boilers did not develop sufficient steam for the output required.——At the meeting of the North St. Pancras Ratepayers' Association, the action of the Joint-Committee, appointed by the Vestry, on the subject of erecting an additional central station in King's-road, was approved.

SCARBOROUGH.—Subject to the approval of Mr. Bernard Drake, the electrical engineer to the Town Council, permission has been given to the local Electric Lighting Company to lay their mains and complete the necessary work for the public installation. The Council discussed the alterations made by the Board of Trade in the draft deed for the transfer of the electric lighting undertaking from the Corporation to the Scarborough Electric Supply Company, the Council disapproving of the Board of Trade's alterations.

TIVERTON.—A letter was read at the last meeting of the Town Council by the Mayor, which he has received from Mr. Amory, a resident, suggesting that a Guarantee Society should be formed of those persons willing to adopt the electric light, in order to obviate any burden upon the ratepayers. He suggests the guarantee should be for three years, and that during that period tradesmen and others using the light should agree to pay 9d. per Board of Trade unit, and that a first charge upon the profits of the scheme should be a refund to the consumers of any sums paid by them exceeding 6d. per unit. The letter was very favourably received, and was ultimately referred to the Electric Lighting Committee for consideration.

WOLVERHAMPTON. — With reference to the electric lighting scheme, as stated in our last issue, Mr. F. Harman Lewis, late of Hull, has been appointed electrical engineer, at a salary of £300 per annum, and Mr. A. P. Brevitt, of Wolverhampton, has been appointed architect, to prepare plans and specifications for the necessary buildings in connection with the scheme, at an inclusive remuneration of 5 per cent. on the building contract. Mr. Brevitt designed the Oxford Station, a copper depositing works at Greenwich, and special works at Wednesfield for making phosphorus by electricity.

WORCESTER.—The Watch Committee have appointed Mr. W. H. Preece to supervise the electric lighting works, at a commission of 2½ per cent. on the amount of the Brush Company's contract.

YEADON.—The Local Board have decided to accept the offer of Messrs. Andrews and Preece (Limited), of Bradford, to furnish an estimate, free of cost, for lighting Yeadon electrically.

PATENT RECORD

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

May 29, 1893.

10,474. J. S. BOLTON and T. J. MURDAY. Gateshead-on-Tyne. Improvements in the construction and form of accumulators for the storage of electrical energy.

10,501. C. A. PRICHARD. London. Improved method of heating liquids by electricity.*

May 30, 1893.

10,533. J. T. JOHNSON. London. Improvements in electrical signalling and printing telegraph systems, and in apparatus employed therein. (Alfred Samuel McCaskey, United States.)*

10,569. R. E. BELL, CROMPTON, and H. J. DOWSING. London. Improvements in means or apparatus for regulating the temperature of electrical heating, cooking, or like apparatus.

10,584. A. T. CASTNER. London. Improvements in connection with electrolytic apparatus.

10,594. T. B. BROWN. London. A novel method of ornamenting or decorating the bulbs of incandescent electric lamps.

10,597. G. S. SLUCE. London. Improvements in devices for adapting electric lamps to ordinary candle fittings, and the like.

10,615. J. HINES. Liverpool. Improvements in telephony, or means for transmitting telephonic signals through long distances.

10,623. D. MURRAY. London. Improvements in printing telegraphs.

10,630. J. ODDY. London. An improved material or combinations of materials to be used for the manufacture of electric arc candles, applicable also for the manufacture of brushes or collectors of dynamos or electric motors.

May 31, 1893.

10,648. G. MITCHELL. London. An improved combined electric light and heat stove.

10,696. H. H. LAKE. London. Improvements in insulators for electric wires. (Eugen Hartmann and Wunibald Brann, Germany.)

6,468. SIEMENS BROS. and Co. (Limited) and NEBEL. Electric arc lamps.
6,703. KOCH. Dynamo brushes.
6,952. MITCHELL. Electrically heated crucibles.
7,758. KLOSS. Electric fire alarm.
7,865. THOMSON. Lightning arresters.
7,866. THOMSON. Lightning arresters.

COMPANIES' MEETINGS.

Consolidated Telephone Construction and Maintenance Company (Limited).

The twelfth annual general meeting of this Company was held on Monday, at Winchester House, Old Broad-street, under the presidency of Mr. C. L. W. FitzGerald.

The SECRETARY (Mr. Charles Curtoys) having read the notice calling the meeting,

The CHAIRMAN said: Gentlemen, we were a little late in getting the report out, but that was simply a question of the auditors. From that report you see that the profit for the year amounted to £4,861, and adding

Digitized by Google

the amount brought forward, it makes £6,228 to be dealt with at the present moment. You observe, a little lower down in the report—some of you, no doubt, attended them—that we passed resolutions at extraordinary meetings for the payment of a certain sum of money for the preference shares and the ordinary shares which we received from the Austrian Company. If you look at the balance-sheet, you will see that the Austrian Company has paid us the sum of £47,675, leaving £2,325 more to pay. The reason for the delay in the payment of that £2,325 is purely a question of accounts, to be settled by the Austrian Company with the Austrian Government; and here I might remark that we called our meeting for to-day because we had hoped to have been in a position to tell the shareholders that we had received the sanction of the Court to return them that capital. However, you are, no doubt, aware that in legal matters you cannot hurry the lawyers. We have now been four months over the matter, and are told that it will still take another month. I now come to a paragraph in the report which I regret very much, for we are not doing so well in the manufacturing department as we have been doing. I can assure you that arises only from one cause; I will not say foreign competition only, because it is competition of English firms also. They keep cutting down the prices of telephones, and the Directors are absolutely powerless. We must sell at the reduced quotation, or not at all. It is an absolute fact that the volume of business turned out at the factory last year and this year was practically the same, but the profit is reduced from £6,000 to £1,848. That is a very serious item, but all we can do is to manage the business as economically as we can, and do the best we can for you. The whole of the Board are very largely interested in the shares of the Company. I myself have something over 7,000 shares, so you can imagine that we are anxious to do well for you. You will see that we have again given up half our fees for the benefit of the shareholders. So far as our agency business is concerned, I think we may be fairly satisfied, and also with the wire rental business. Of course, all these things in the beginning are very slow, but still the business is in England to be got; and if it were not for the foreign competition in the manufacturing department, I think that the affairs of the Company would look in a fairly satisfactory position. Our only remaining subsidiary company working a telephone exchange is the Anglo-Portuguese, which is doing fairly well, and steadily progressing. It pays a dividend of 5 per cent. on its ordinary share capital, in addition to paying us a dividend on the debentures we hold. I am pleased with the Anglo-Portuguese Telephone Company for this reason—that it has been a steady drain on this Company in finding it money up to date, and now we see that we are getting that money back. I think that that is a fairly satisfactory point. I do not think that there is any particular item to which I need call your attention in the accounts, excepting the one of expenses. They have been considerably reduced, and they will next year show a further reduction, for this reason—that in the present statement we only show one half-year of the reduction we made at the date of our last meeting. I might mention that we are owed the sum of £8,813, while we owe only £998. That, I think, is very satisfactory. You can see for yourselves that we have a very large sum of money in hand, which we hope to return very shortly to the shareholders. I now propose—"That the annual statement of accounts and balance-sheet, with the reports of the Directors and auditors, as now submitted to the meeting, be received and adopted, and that a final dividend, at the rate of £5 per cent. for the half-year, making £6 per cent. per annum, be paid on the preference shares, and £2 per cent. per annum be paid on the ordinary shares, for the year ending March 31, 1893, as therein recommended."

Sir A. ARMSTRONG, K.C.B., seconded the motion.

Mr. HIBBERT observed that he had nothing to say against the Directors, for he felt that they had done all they could. He thought, however, that they were working the manufacturing department at a loss. They were now going to pay off the preference shares and to write down the capital to £112,000, in 224,000 shares of 10s. each. If they made a profit afterwards on the present basis it would only amount to 2 per cent., and the question was whether it was worth while going on, unless the Chairman hoped—as he himself did—that there was some chance of extra profit coming to them. As far as he could see, the patents were altogether gone, and there was no goodwill now, and he did not think that they were justified in entering the item as goodwill.

The CHAIRMAN: The hon. shareholder has referred to a figure in the balance-sheet which we had absolutely nothing to do with.

Mr. HIBBERT said he was aware of this.

The CHAIRMAN: There is that £73,000 staring us in the face, and it was something beyond that, only we have reduced it. The figure was put there by another set of gentlemen altogether. If I had had anything to do with the Company at the time it would never have been put there. The shareholder suggested that it should be written down, but if you do that you must write down your capital on the other side. I do not know how that would meet with the approval of the shareholders. Personally, I do not care whether you have your shares at 5s. or 10s.; it is the profit on the shares that I look to. We are going to write off some of this item, however. As to the future, I do not care to be a prophet. I hope we shall do better, but it is very difficult to prophesy. I am not a merchant, and have not met with anything in the shape of foreign competition until now, and I must say that that competition is worse than I anticipated. If you take only the manufacturing and only the expenses on the other side, you are working at a loss; if you do not take the securities you hold as worth anything, then you are working at a loss.

Mr. WALKER inquired whether the Company had any claim against the National Telephone Company on account of its instruments.

The CHAIRMAN: No.

On the motion of Mr. BUCKINGHAM, seconded by Mr. ARTHUR BAKER, the retiring Directors, Mr. Fitzgerald and Mr. Henry Grewing, were re-elected.

Mr. BUCKINGHAM said that with respect to working at a loss, it was only fair to say that as the figure was shown, a loss was practically apparent. At the same time, it was not fair to charge all the expenses to the manufactory, and if that view were taken, a small profit would be shown. He hoped that their next balance-sheet would be found more acceptable.

The CHAIRMAN then proposed the re-election of Mr. J. G. Griffiths as auditor.

Sir A. ARMSTRONG seconded the motion.

A SHAREHOLDER said he desired to protest against the large fee that was paid to the auditors. The profit of the Company was very small, indeed there was almost a loss, and as the Directors had voluntarily given up part of their fees, he thought the auditors ought also to show some sacrifice. He proposed an amendment to the effect that only one firm of auditors should be appointed, and at the salary of 50 guineas.

The CHAIRMAN said that there was no absolute necessity for two auditors, but he had reminded the shareholders a good many times that in 1884 they desired to have two auditors. He thought that the shareholder was hardly in order in moving his amendment, as he had not given previous notice to the Directors of his intention to do so. The Board would, however, approach the auditors, and see if they would not reduce their remuneration.

Mr. J. G. GRIFFITHS said that he was not at all anxious to be re-elected, especially if there was the slightest dissent. The duties and responsibilities were considerable, and he was quite confident that his firm were not over paid for their work. He regretted that he was not able to accept a reduced remuneration, but he was prepared to retire at once if the shareholders wished it.

The CHAIRMAN said that, personally, he would regret losing either of their auditors, although he had said candidly that two auditors were not absolutely necessary.

Mr. GRIFFITHS said he would be very glad if Mr. Green's name were put first to the meeting, if it was only intended to re-elect one of them.

A SHAREHOLDER remarked that Mr. Griffiths had been an auditor from the first, and that his name ought, therefore, to be put to the meeting first.

The CHAIRMAN then submitted the name of Mr. Griffiths for re-election, and declared it carried with one dissentient.

A SHAREHOLDER afterwards proposed the re-election of Mr. Green.

The CHAIRMAN seconded the motion; but having put it to the meeting in the usual way, he announced that Mr. Green was not re-elected.

On the motion of Mr. WALKER, a vote of thanks to the Chairman was passed; and

The CHAIRMAN having briefly acknowledged the compliment, the proceedings terminated.

The following is the report of the Directors:—

The report and accounts of the operations of the Company for the year ending March 31st showing a net profit of £4,861. 17s. 10d., which, with the amount carried forward, leaves a balance of £6,2 8. 6s. 7d. for disposal, after making provision for doubtful debts. Your Directors propose to pay a dividend of 2 per cent. for the year on the ordinary shares, and 3 per cent. on the preference shares for the half-year, making 6 per cent. on that class of share for the year: writing off the sum of £357. 18s. 9d. for depreciation of plant, machinery, and furniture; also £63. 16s. 8d. from the cost of new building, and reserving £19. 11s. 9d. for rentals paid in advance, thus leaving a balance of £1,117. 13s. 6d. to carry forward. The Board regret that, though the volume of work turned out from the factory has been much the same as last year, the profit has been very much decreased by foreign competitors offering instruments at lower prices. The Directors have again unanimously resolved to relinquish one-half of their fees for the year ending March 31st. The agencies established have proved fairly remunerative, and the private wire rental business is showing satisfactory expansion.

The remaining subsidiary Company, the Anglo-Portuguese Telephone Company, in active operation in exchange work, has, considering the state of affairs in Portugal, done very well, the progress being shown by the following statement:—

Year ending March 31st.							
Subscribers.		Rental.		Increase.			
1892.	1893.	1892.	1893.	Subscribers.		Rental.	
2,139	2.249	£13,640	£14,447	110		£837	

Birmingham Central Tramways Company (Limited).

Mr. Joseph Ebbsmith, Chairman of this Company, has issued a circular to the shareholders, of which the following is an abstract:—

"Herewith you will receive notice of a special meeting, which will be held on June 21st, for the purpose of considering certain proposals to alter the Articles of Association of the Company. As your mind may have been disturbed by recent reports on the state of the Company's affairs, I desire to make this report upon the duties which you entrusted to me in 1887, and which I now claim to have fulfilled. When I became Chairman of the Company my efforts to avert liquidation were ridiculed. It was pointed out that the contracts and commitments of the Company far exceeded its available assets. This I admitted; but expressed my opinion that, with prudent administration, the earning capacity of the Company was sufficient to avert its collapse, even though it might not be sufficient to return the capital expended. In 1888 I was urged to reduce the capital of the Company, but I declined to recommend any such reduction.

"The present position of the Company is accurately shown by the fact that our engagements, which at one time were so serious, have been fully

Digitized by Google

met. The whole of the capital commitments have been discharged. There is not at the present time a single obligation of the Company for which ample provision has not been made. We have repaid our bankers the advances which they made after full inquiry into the position of the Company, and we have now more than £24,000 of debentures available for issue if required. During the past six years the present Board have paid on capital account more than £160,000. The Company has paid its debts and has fulfilled its contracts; and the time (foreshadowed by me in 1888) has now arrived when the shareholders should calmly and dispassionately consider the question of reduction of the ordinary capital of the Company to the amount upon which a reasonable dividend may be certainly expected. I think you may safely disregard extreme opinions on this question of reduction of capital.

"In 1887 the working profits were under £20,000 per annum. In 1888 they rose to £30,000; and now an average of £45,000 may be reckoned on, which, after payment of rent, interest, and preferential dividend, allows an annual reserve of £10,000, and leaves £10,000 for division among the ordinary shareholders, representing 5 per cent. on £200,000; and I therefore recommend a reduction of the ordinary capital from £400,000 to £200,000, that is for each ordinary share to be £5 in lieu of £10. You will find a share paying 5 per cent. is more marketable than one paying only 2½ per cent., whatever the nominal amount.

"The meeting to be called is for the purpose of making certain alterations in the Articles of Association, which is necessary before a reduction of capital can be effected. No less than four meetings may be necessary—the first to authorise the alteration in the articles; the second to confirm the resolution; the third to determine by resolution the amount of the reduction; and the fourth to confirm that resolution.

"Let me assure you most emphatically that my impending resignation is not caused by anxiety as to the present position of the Company. The cause is purely personal, and the new Board may, at any time, rely upon my goodwill and readiness to advise them upon any question within my special knowledge. I would point out to my critics, whether friendly or unfriendly, that there is a local as well as a financial aspect of the work which I have done for the Company. Had the Company passed into liquidation in 1887, when the gloom of the Cab Company failure hung over Birmingham, the double catastrophe would have more than doubled the financial scandal. I took the chair, I pledged my tramway reputation that the Company was a solid profit-earning undertaking, and I have the satisfaction of knowing that my colleagues and I have not only saved a substantial amount (£5 per share means £200,000) for the ordinary shareholders, but have also done our best to avert a foul blow upon the commercial credit of Birmingham."

Accompanying Mr. Ebbsmith's circular is another dealing with certain statements made by a Mr. J. T. Mantle, acting as Chairman of a "Shareholders' Committee," censuring the Board for their action in introducing electricity into the Bristol-road section of their system "against the advice of the Company's engineers." This the Directors deny, and are supported in this denial by letters from both Mr. E. Pritchard and Mr. J. Kincaid, the engineers referred to. It appears to have been a question entirely of finance, £40,000 being the estimated cost of accumulator traction, and £80,000 for cable traction. The Directors contend that the then (1888-9) financial condition of the Company rendered it impossible to raise the larger sum.

The Shareholders' Meeting will take place at the Queen's Hotel, Birmingham, on Wednesday, June 21st, at 12:30 o'clock.

Elmore's Wire Manufacturing Company (Limited).

An extraordinary general meeting of this Company was held on Monday at Winchester House, E.C., Mr. F. J. Atkinson presiding.

The CHAIRMAN said the report of the Committee of Investigation appointed by the general meeting of the shareholders was issued in April last, when it would be seen that, if the working capital required was fully subscribed, there was every prospect of good success for the Company. The Board and Committee jointly made an issue of £25,000 of Six per Cent. First Mortgage Debentures, which, however, were insufficiently subscribed. The Board submitted a scheme to some of the larger shareholders, and this was approved, as would be seen from the resolution passed on a previous occasion. The provisional applications for the preference shares, however, had been comparatively few, and fresh negotiations had been opened up with other parties for an advance of the sum required to relieve the Company from its liabilities, amounting to £15,000. These negotiations had been carried on through Mr. Hay, whose offer stipulated that the Board should get the additional capital required to carry on the works without delay. It would be necessary, therefore, that the resolution referred to should be passed, and certain of the shareholders had agreed to assist the Board in the capacity of a consultative committee. The scheme would, in a measure, meet the views of those shareholders who contended that, as the preference shareholders were to take so large a share of the profits, only the least possible number of preference shares should be issued. The Chairman then submitted a resolution, that 16,500 unissued ordinary shares of the Company should be issued, to be called preference shares, carrying interest at the rate of 10 per cent. per annum, and to one-half of such remaining profits in each year as should be applicable to the payment of a dividend on the capital paid up on the shares of the Company other than the founders' shares; such preference shares to be entitled to priority not only as to dividend, but also as to capital on a distribution of the Company's assets.

The motion was seconded by Mr. ELMORE, and opposed by General BEADLE and Mr. BARKWORTH, but eventually agreed to.

A consultative committee of shareholders was appointed to confer with the Board.

Printing Telegraph and Construction Company of the Agence Havas (Limited).

The statutory general meeting of this Company was held on Wednesday last at the Company's offices, 12, King William-street, E.C., Colonel W. J. Engledue (the Chairman) presiding.

The SECRETARY (Mr. Theodore J. Ford) having read the notice convening the meeting,

The CHAIRMAN said: Although the usual four months from the date of the registration of the Company has not elapsed, your Directors have thought it advisable to convene the statutory meeting in order to explain the position of the Company, and the difficulties which have arisen owing to the hesitation to fulfil their obligations on the part of a considerable proportion of those who undertook to subscribe the necessary capital. We proceeded to allotment on total applications for 12,177 shares, representing £60,885; but I regret that several subscribers have failed to pay, and in order to carry out the objects of the Company it has been necessary to take legal proceedings against some of the defaulters. This disappointing result prevented an immediate settlement with the vendors and promoters, and also prevented the acquisition by the Company of the patent, for which the vendors had agreed to pay the patentee £7,000 in cash and a proportion of their fully-paid shares, as the Directors could neither part with cash nor issue shares to the vendors, as their contract was not fulfilled. After six weeks' waiting for a settlement, the patentee reluctantly cancelled his agreement with the vendors and promoters. We then rescinded the original contract, and were able to acquire the patent from another source without payment of any cash. I understand the patentee had sold for shares only, showing his complete confidence in his invention. Mr. Wright, the patentee, has throughout acted with the greatest patience and consideration, and the new vendor has, I am told, arranged to make over a proportion of the fully-paid shares, issued to him, to such of those persons interested with the former vendors who are worthy of such consideration. He has also materially assisted the Directors by placing in trust £10,000 of his fully-paid shares to meet any deficiency in the subscription of the £40,000 working capital, should the Directors be unable to collect these liabilities from defaulting shareholders. It, therefore, only remains for the shareholders to pay the calls now due to enable the enterprise to proceed to a successful issue. The shareholders are aware that the Agence Havas holds the leading position in France as a news agency. For many years it has enjoyed the confidence of the leaders and representatives of every form of Government in France; it receives the earliest and most reliable political news, and is probably the only organisation of the sort to which the French Government would grant such concessions as have enabled the Company to be started. Rival agencies have attempted to obtain similar rights to enable them to introduce inferior printing telegraph machines into Paris, but have failed, the result being an undercurrent of intrigue, having for its object the wrecking of their undertaking. When the Company was registered, the Agence Havas had received many applications for the printing telegraph machines, and were canvassing for further support; but as complications arose which threatened to delay our progress indefinitely, it was necessary to desist from taking orders which it would be impossible to execute. There were 66 actual subscribers, who will pay a yearly rental of 105,700fr., making an average of 1,600fr. per subscriber. Amongst these clients are banks, clubs, and hotels. As all subscriptions are to be paid in advance, on the receipt of machines, we are, I think, commencing business on favourable terms. Bearing in mind the financial complications that have arisen, and pending the result of the legal proceedings against defaulters which your Directors have been reluctantly obliged to take, it has been thought advisable not to estimate for more than 125 machines at first. These will be arranged on ten circuits, which will be capable of accommodating more machines as necessity arises. These circuits have been very carefully worked out under the direction of M. Houssaye, our manager in Paris. Tenders are now being invited in Paris for the cable necessary for the circuits, and 125 machines are in course of manufacture in New York. If, after this meeting, the shareholders come forward at once and meet their obligations, the first installation of machines could be fixed within about four months from this date. If, however, there should be delay, the Directors will hesitate before accepting any tender or incurring expense. Delay will cause great uneasiness amongst those who have promised to take the instruments, and might prevent the Agence Havas from pushing the business. The Directors consider the prospects even better than those foreshadowed in the prospectus. I have no accounts or business to place before you at this meeting. Mr. C. Cammell, one of the original Directors, has resigned his seat, and Count Max Hollender has consented to consider if he can fill the vacancy.

Mr. EDWARD MOXON blamed the Board for going to allotment on too small a subscription.

Mr. MAY (the solicitor), in reply to a question, stated that the Company was in legal possession of the patent.

Count MAX HOLLENDER stated that he was not anxious to join the Board, and only proposed to do so because several of his friends were large shareholders.

The CHAIRMAN next read a letter from Mr. John Burke (one of the contractors), who "was unable to attend the meeting, but who had seen two of their machines at work in Paris. These were not of the latest pattern, one of them having been in use in Paris for nine months; but both seemed to run very smoothly, and were so simple that there was evidently nothing likely to go out of order. He felt decidedly encouraged by what he saw."

Mr. BEYFUS suggested that one vacancy on the Board be filled up by appointing Sir Augustus Harris.

In reply to Count Max Hollender, the CHAIRMAN stated that to lay down 125 machines, including the cable and other expenses, would cost the Company about £10,000, and it was proposed to call up £1 per share at once, and another £1 per share in two months' time.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1893, pages 320-348, *&c., &c.*]

DAIMLER MOTOR SYNDICATE (LIMITED).—This Company was registered on May 26th, with a capital of £6,000, in £10 shares, to carry on the business of engineers, &c.

FORD-LLOYD MANUFACTURING COMPANY (LIMITED).—This Company was registered on June 7th, with a capital of £10,000, in £1 shares, to acquire and take over as a going concern the business of electrical engineers, and manufacturers of electrical appliances, carried on by the Ford Lloyd Manufacturing Company, at Mount Pleasant, Clerkenwell, London, E.C., and at Penarth Works, Bermondsey, S.E.; to acquire and sell the invention known as the "E.S. Dry Battery," and to carry on business as an Electric Light, Heat, and Power Supply, and Telegraph and Telephone Company. The subscribers are:—Arthur Ford-Lloyd, E. J. Tumber, C. H. Elliott, E. P. Grove, A. Grundy, W. M. Foxcroft, and E. A. Herbert. The first directors are:—E. J. Tumber, A. Ford-Lloyd, and C. H. Elliott, who are also managing directors, with a salary of £200 per annum each.

FOSTER BROTHERS (LIMITED).—Registered, with a capital of £30,000, in £10 shares, to acquire, as a going concern, the business of tube manufacturers and galvanisers, now carried on by H. Foster, J. F. Green, and J. Foster, and to carry on and extend the same.

"INDUSTRIES" AND "IRON" (LIMITED).—A Company was registered on May 24th, with a capital of £90, divided into 1,800 shares of 1s. each, to acquire the copyright and goodwill of the two journals known respectively as *Industries* and *Iron*, and with a view thereto to enter into an agreement with Mr. C. Arthur Pearson, of *Pearson's Weekly*, *Search-Light*, *Society News*, &c.

MERIONETHSHIRE ELECTRIC LIGHTING, POWER, AND APPLIANCE COMPANY (LIMITED).—This Company was registered on June 9th, with a capital of £3,000, in £1 shares, to adopt and ratify an agreement between A. Hall and Co. and F. H. Handy on behalf of the Company, and to establish and carry on at Dolgelly and elsewhere the business of supplying electricity for the purposes of lighting, heating and motive-power, and to carry on the business of electricians, mechanical and electrical engineers, and manufacturers of, and dealers in, all apparatus and things required for, or capable of being used in connection with the generation, distribution, supply, accumulation, and employment of electricity. The subscribers are:—H. May, W. Williams, J. C. Roberts, F. Whiteley, H. W. Brethertion, A. Thorburn, F. H. Handy. The first Directors are:—J. C. Roberts, W. Williams, F. Whitely, A. Thorburn, Henry May, and Dr. Lloyd Williams, of Dolgelly.

PIONEER ELECTRIC CARRIAGE COMPANY (LIMITED).—This Company was registered on June 8th, with a capital of £20,000, in 400 shares of £50 each, to enter into an agreement to be made between the Electrical Power Storage Company (Limited) and the newly-formed Company, to acquire, develop, and turn to account letters patent, patent rights, inventions, and other privileges connected with the propulsion of vehicles and carriages on tramways, highways, and roads by means of electricity, to construct or otherwise acquire vehicles propelled by electricity or otherwise, to obtain licenses for the same under the Hackney Carriages Acts, and to let the same for hire, and carry passengers and goods. The subscribers are:—J. Irving Courtenay, F. King, J. W. Barclay, Sir. Geo. R. Prescott (Bart.), Major-General Chas. E. Webber, Sir Daniel Cooper (Bart.), and F. Green. The first Directors are to be nominated by the signatories.

RICHARD POORE AND CO. (LIMITED).—Capital £6,000, in £1 shares Objects: To carry on the business of electrical engineers, engineers, electricians, suppliers of electricity for the purpose of heat, light, motive-power, &c.

SIR WILLIAM ARROL AND CO. (LIMITED).—This Company has been formed to purchase the business of contractors and engineers carried on at Glasgow and elsewhere, with a capital of £150,000, in £10 shares.

BRUSH ELECTRICAL ENGINEERING COMPANY (LIMITED).—The annual return of this Company, made up to October 14th last, has been filed. The nominal capital consists of 150,000 ordinary shares of £3 each, and a like number of preference shares of £2 each. 78,383 ordinary and 75,000 preference shares have been taken up, and the full amount called, resulting in the total payment of £385,149.

DISTRICT MESSENGER SERVICE AND NEWS COMPANY (LIMITED).—In consequence of the acquisition of the business of the Boy Messengers and Electric Call Company (Limited) this Company, on June 9th, increased its nominal capital from £200,000 to £275,000, in £1 shares, pursuant to a resolution passed April 24th.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY (LIMITED).—The annual return of this Company, made up to May 3rd, shows that 250,000 out of the 300,000 shares, of £10 each, have been taken up, the full amount called, and all calls (£2,500,000) paid.

ELECTRIC STORES (LIMITED).—The annual return of this Company, recently filed, shows that the seven original signatories are the only shareholders out of a nominal capital of £15,000, in £1 shares.

ELECTRIC TRAMWAYS CONSTRUCTION AND MAINTENANCE COMPANY (LIMITED).—Although this Company was registered in 1886, with a capital of £250,000, in £1 shares, the last return, made up to May 8th, shows that the signatories' shares are the only ones taken up, no calls having been made.

ELECTRICAL WORKS CONSTRUCTION AND MAINTENANCE COMPANY (LIMITED).—Mr. P. A. Latham, acting secretary of this Company, informs the Registrar of Joint-Stock Companies that the Company has never done any business, and that the seven members constituting the concern desire that the Company be struck off the register.

ELMORE'S FRENCH PATENT COPPER DEPOSITING COMPANY (LIMITED). A petition was presented on the 2nd inst. for the winding up of this Company, and is down for hearing on Wednesday next, the 21st inst.

FOREIGN PILSEN ELECTRIC LIGHT AND POWER COMPANY (LIMITED). The annual return of this Company, made up to March 14th, shows that 29,800 shares out of a total capital of £30,000, have been taken up, and all have been issued as fully paid to the shareholders of the Union Electric Light and Power Company (Limited).

WESTERN COUNTIES AND SOUTH WALES TELEPHONE COMPANY (LIMITED).—A meeting will be held at 5, Moorgate-street, E.C., on July 20th, at 2 p.m., to receive an account of the winding-up.

CITY NOTES, &c.

CALLS DUE.—*June 27:* EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY (LIMITED), 20 per cent. on £200,000 Four per Cent. (Mauritius Subsidy) Debentures of £25 each.——*June 30:* BRUSH ELECTRICAL ENGINEERING COMPANY (LIMITED), final £1 on 10,000 new ordinary £3 shares, and final 10s. on 15,000 new Six per Cent. Preference Shares of £2 each.; NATIONAL TELEPHONE COMPANY (LIMITED), 25 per cent. on £273,523 Four and a-Half per Cent. Debenture Stock.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended June 11th were £759, as against £745 for the corresponding period of last year, being an increase of £14. The total receipts for the half-year amount to £20,252, against £18,614 in the corresponding period of 1892, being an increase of £1,638.

COMMERCIAL CABLE COMPANY.—The Board announce a quarterly dividend of 1¾ per cent., payable on July 1st.

BIRMINGHAM MINT (LIMITED).—At the annual meeting, held at Birmingham on Thursday, a dividend of 7 per cent. was declared. The Chairman, in moving the adoption of the report, said the depression in trade had seriously impaired the profits, and the fall in price of spelter and copper made a loss of £1,400. The profitable branch of the business had been not minting, but seamless tubes and other special manufactures.

DAN RYLANDS (LIMITED).—The Directors of this Company regret to announce the resignation of Mr. Dan Rylands as a Director. Mr. George Herbert Peake, of the Strafford Collieries, Barnsley, has been elected to Mr. Rylands's seat on the Board. This resignation will not in any way affect the business of the Company, who are well known as makers of glass-lined tubing, electrical glass wire, &c.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY (LIMITED).—The coupon on this Company's Five per Cent. Australian Government Subsidy Debentures, due on the 1st July prox., will be paid on and after that date by Messrs. Barclay, Bevan and Co., 54, Lombard-street, E.C. Coupons must be left three clear days for examination.

EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY (LIMITED).—Letters of allotment for the recent issue of £200,000 Four per Cent. (Mauritius subsidy) Debentures have been posted.

ELECTRIC AND GENERAL INVESTMENT COMPANY (LIMITED).—Notice is given by this Company that the transfer books and registry of members will be closed from the 13th to the 27th inst. for the purpose of preparing dividend warrants.

GENERAL ELECTRIC COMPANY (NEW YORK).—American advices notify extraordinarily heavy sales of general electric stock, for which friends of the Company are at a loss to account.

NATIONAL TELEPHONE COMPANY (LIMITED).—Sir Albert K. Rollit, M.P., has joined the Board of this Company.

SOCIETE GENERALE DES TELEPHONES.—An extraordinary general meeting of the shareholders was called for yesterday (Thursday) to consider a scheme of reconstruction, under which the Company would be wound up and a new Company formed with a reduced capital of 15 million francs. The old Company will only continue to exist for the purpose of carrying on its actions in the law courts against the Municipality of Paris, and against the Government. The shareholders are to receive, for each five shares they now possess, three of the new Company and five bonds in the liquidation, these latter representing the shares in the old Company in the distribution of the sums receivable from the Government and the Municipality.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee have ordered ordinary shares Nos. 1 to 15,000, and Six per Cent. Preference Shares Nos. 1 to 28,000, of the Monte Video Telephone Company (Limited) to be quoted in the official list,

Digitized by Google

SWAN UNITED ELECTRIC LIGHT COMPANY (LIMITED).—The Directors have resolved to pay an interim dividend at the rate of 5 per cent. per annum in respect of the six months ended March 31, 1893, as follows: 1s. 9d. per share on the 78,949 ordinary shares of the Company (£3. 10s.), and 2s. 6d. per share on the 19,750 £5 fully-paid shares, free of income-tax. Warrants will be issued 20th inst.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended June 9, 1893, after deducting 17 per cent. of the gross receipts, payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,768.

WESTERN UNION TELEGRAPH COMPANY (LIMITED).—This Company have declared their usual quarterly dividend of 1¼ per cent.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 788.—Vol. XXXI. FRIDAY, JUNE 23, 1893. PRICE FOURPENCE.
Annual Subscription (U.K.), 19/6

NOTES.

The Joint Committee of both Houses of Parliament, appointed to consider the prohibitions and restrictions which the National Telephone Company seek to impose upon those who obtain statutory powers to use electricity, have been sitting during this week. The members of this Committee, who are well qualified to consider the important questions before them, have already shown by their questions that they take a practical view of the subject. If the traction companies succeed in putting their case as fully as the National Telephone Company has done, their claims will have every chance of being exhaustively considered. The evidence of the railway companies, though at first rather alarming, ought to be disposed of without difficulty. Nor should there be any obstacle to the protection of the interests of the gas and water companies. They are more seriously threatened, though they have only just become aware of it.

The article appearing in this issue containing Mr. Rimington's ideas as to the cause of luminosity in vacuum tubes possesses several interesting points, but we are still of opinion that in these discharges the distinction between the electrostatic and electromagnetic parts of the phenomena has not yet been at all clearly demonstrated by any experimenter. Probably this will not be accomplished till the behaviour of electrostatic lines of force is more studied. It is curious that while the science of magnetism has been developed mainly by paying attention to the behaviour of magnetic lines, it has been found more convenient to study electrical phenomena by considering the distribution and motion of quantities of electricity. It is quite as uncommon to find in books any reference to tubes of electrostatic induction as it is to find magnetic phenomena explained by means of magnetic charges. Prof. J. J. Thomson has in some recent Papers drawn attention to the importance of the study of these electrostatic lines, or Faraday tubes, as he calls them; and in his new book, entitled "Recent Researches in Electricity and Magnetism," he makes considerable use of Faraday tubes in explaining the phenomena of the passage of electricity through gases. Prof. Thomson's important work will probably, as one of its results, have the effect of directing study to this, as yet, little used method of investigating the subject.

We have received a pamphlet describing a new French mathematical journal, the first number of which is to appear with the new year. The speciality of this publication is that it is to consist of two portions, one of which is to contain the particulars of useful or interesting problems which have as yet *not* been solved, while the other will deal with the previously published problems, and give such solutions of them as the readers of the journal have been able to supply. Mathematical articles of the ordinary kind will not be published, as those which appear will all have a direct bearing on the problems printed in previous numbers. The journal will provide its readers with plenty of material on which to exercise their analytical talents. It will also afford a means of drawing public attention to a problem in the solution of which a reader may be particularly interested. This journal deserves a favourable reception, as it will have a distinct tendency to increase the usefulness of mathematical work. Like all other branches of science, mathematics has become too much specialised, and the new publication should correct this tendency by suggesting problems of more general interest. It should also enlarge the number of applications of methods, which might otherwise remain unknown except in the special parts of mathematics in which they have been discovered. It is to be hoped that the financial difficulties which must occur in supporting a magazine of this kind will be successfully overcome. As regards the printing, which is specially important in connection with mathematical journals, the promoters are to be congratulated on having secured the support of the firm of Gauthier-Villars et Fils of Paris, who will bring out the journal under the title of *L'Intermédiaire des Mathématiciens*.

Among the original communications appearing in the June number of the *Journal* of the Institution of Electrical Engineers is one entitled "Some Advantages of Connecting the Coils of Electromagnets in Multiple Arc." A perusal of this article shows, however, that the advantages in question are imaginary. The writer considers the case of two similar electromagnets, each with 1,000 turns of wire, arranged in series in one case, and, in the other, in two sets of 500 turns joined in parallel. He then shows that, if the magnets are excited by the same current, the number of ampere-turns is twice as great in the former case as in the latter, while the energy spent is no less than four times as much. But this is no advantage in favour of the magnet with parallel winding, for as the heating depends on the square of the current, when the magnets are excited to the same extent, the number of watts spent will be identical in the two cases. The writer appears to have quite

Digitized by Google

overlooked this point. Even, however, if it were true that the energy required for magnetisation could be reduced by the method suggested, it would not show that the arrangement of the coils in parallel is advantageous; it would only prove that magnets should be wound with a few turns of thick wire rather than with many turns of thin.

It is further stated that winding the coils in parallel diminishes sparking and accelerates magnetisation. When the coils joined in parallel are of an unequal number of turns, the self-induced electromotive forces occuring on breaking circuit are unequal, and cause currents to circulate in the coils and to absorb the energy of the magnetised iron otherwise spent in producing sparks. In many cases, therefore, it has been found advantageous to wind magnetising coils in parallel. If, however, these coils are all alike, so that the number of turns on each is the same, nothing is gained by parallel winding that would not be more easily secured by the use of thicker wire. It is, moreover, not true that the rate of magnetisation or of demagnetisation is accelerated by parallel winding. The rate of growth of magnetism depends on the ratio of the self-induction of the circuit to the resistance, and parallel winding diminishes one of these quantities to exactly the same extent as the other.

Some interesting observations dealing with the subject of the dimensions of units have been communicated to recent issues of the *Comptes Rendus* by M. Abraham. His last note on this subject is of considerable value. It is an attempt to establish between the dimensions of absolute temperature, and the fundamental units of length, mass, and time, a connection which is independent of the properties of any physical substance. Previous attempts to arrive at the dimensions of temperature have met with but very slight success, and Prof. Rücker has proposed to provisionally accept temperature as a new fundamental unit, like magnetic permeability or specific inductive capacity. The line of argument pursued by M. Abraham in attacking this subject is original and ingenious. He starts with the fundamental law of electrolysis discovered by Faraday, that the number of ions liberated in a voltameter is dependent merely on the quantity of electricity which has passed through it, and is independent of the nature of the ion. There is a definite amount of electricity associated with a molecule of gas whether this gas be oxygen, or hydrogen, or any other, and M. Abraham proceeds to inquire whether there is any other property which, in a similar way, is common to all gases.

A relation of this kind is to be found in the simple connection which exists between the pressure, the absolute temperature, and the volume occupied by any given amount of any one of the permanent gases. This relation is that the product of the pressure and volume when divided by the absolute temperature yields a quotient pv/T which is invariable for the same quantity of the gas in question. M. Abraham accordingly points out that if a quantity Q of electricity is used to decompose *any* gas from an electrolyte and the value of pv/T be found for the gas decomposed the number which represents the quotient is proportional to Q under all circumstances, and is quite independent of the nature of the gas. This relation is a very remarkable one, whether we are, or are not, willing to admit the legitimacy of the next step which M. Abraham takes, namely, to equate Q to pv/T and to arrive at the dimensional equation $T = pv/Q$. If we admit the correctness of this procedure we must inevitably conclude that temperature is identical, dimensionally, with electrical potential. It is, however, not at all evident that the well-known law pv/T is a constant for the same quantity of gas, is sufficiently complete to justify the conclusion drawn from it. In the equation above, some other physical quantity may have had its dimensions "suppressed" just as those of magnetic permeability are even now often ignored in electrical equations.

In a Paper recently presented to the American Institute of Electrical Engineers, Lieut. Parkhurst suggests a few modifications in the construction and use of galvanometers of the d'Arsonval type. Of these, the only suggestion calling for any comment is the proposal to use a telescope and scale in place of the more usual arrangement of a ray of light focussed on to a scale by means of a concave mirror attached to the moving part of the instrument. There are, no doubt, great advantages in using the telescope method. Measurements can be made in this way with greater accuracy than is possible with the ordinary method; and they can, moreover, be performed without darkening the room in which the tests occur. On the other hand, concave mirrors are cheaper than plane ones, and a slight distortion of a concave mirror does not render it quite useless, whereas, unless the mirror employed with the telescope method is fairly large, and accurately plane, good results are impossible. The telescope method needs more expensive apparatus, and is far more tedious in practice. It is always used in laboratories when great accuracy is necessary, but under ordinary circumstances it is found more convenient and quite accurate enough to use a concave mirror. Many of the advantages which Lieut. Parkhurst speaks of can be secured by using a glow-lamp as a source of light, and focussing the filament on the screen by adjusting its distance from the concave mirror on the instrument. This method has been used with excellent results in many test rooms, as it is not really necessary to work in a darkened room, since the image of the filament is quite clearly visible in the ordinary dull light of a factory.

The Late Werner von Siemens.—The German Society of Engineers has issued a circular appealing for subscriptions for a proposed memorial to the late Werner von Siemens.

Cable Interruptions:—

	Dates of Interruption.
Paramaribo-Cayenne	April 15th.
St. Thome-Loanda	May 30th.

Ballarat.—The municipalities of Ballarat West and Ballarat East, dissatisfied with the present arrangements for lighting the public thoroughfares, are taking joint action with a view to the introduction of the electric light as the street illuminant. Mr. Murray, electrical engineer, of Melbourne, has been consulted on the matter.

Electric Traction at Halle.—At the recent meeting of the Halle Tramways Company it was announced that the Company had determined to introduce electric traction on their lines

Digitized by Google

owing to the competition of the electric tramway recently opened, and owing to the fact that the public were exceedingly anxious that this step should be taken.

Electric Cranes for Wool Warehouses.—Until recently the Directors of the Union Warehouse Company, of Bradford, had made use of hydraulic power for working their cranes. They are now to be worked by electricity from the Corporation mains, the severe frosts of the past two or three winters having proved most destructive to the hydraulic plant.

The Electric Lighting of Barrack Yards.—At the barracks in the Mitcham-road four arc lamps have been fixed in the parade ground and one in the drill shed, with a view of obtaining the advantage of being able to practice battalion movements in the dark evenings without being confined to the small space afforded by the drill shed, which has hitherto been the only available space for the purpose.

Electric Cooking.—In a letter to the *Journal of Gas Lighting*, Mr. Thos. Fletcher says that he has no intention to be "down on" electric cooking, as there is no doubt it is simply an introduction to gas fuel. People will, he thinks, take up electric cooking first, and become educated in culinary cleanliness; then they will abandon electric cooking on account of its cost, and take up with gas, because their cleanly instincts will forbid a return to dirty coal fires. *Nous verrons!*

Electric Traction for Canal Work.—We referred in our issue of May 12th to a Bill passed by the New York State Legislature, making an appropriation for the purpose of experimenting with electric traction on the State canals. The Superintendent of Public Works has now issued an order directing that all who wish to submit devices for electric traction for boats must file their applications. Tests will be made, if possible, during the present season of navigation.

Engine Nomenclature.—In an article in *L'Electricien* dealing with that ever-burning question, the relative merits of high and low-speed engines, M. Simon points out that it is necessary to have a clear idea of what we really mean by a high-speed engine: do we mean one with a high piston speed, or one that runs at a high number of revolutions per minute? M. Simon is for denominating what are usually called high-speed engines "high-velocity engines," and restricting the term high-speed engine to one which has a high piston speed.

Melbourne.—The *Melbourne Age* states that the electric lighting station which is being erected for the City Council is fast approaching completion, and will shortly be ready for occupation. The whole of the plant has been landed in the colony, and the engines and boilers are now being placed in position. The whole of the poles for the overhead wires have been delivered, but they will be used until such time only as an underground scheme has been devised and carried out. It is confidently anticipated that everything will be in readiness to make the change from lighting by gas to electricity in about three months.

Copper.—According to Messrs. H. R. Merton and Co. the fresh copper supplies in England and France last month amounted to 7,941 tons, whilst the deliveries were 10,084 tons, the visible stocks in the two countries having been reduced from 52,094 tons at the end of April to 49,951 tons at the end of May; a smaller quantity than that recorded at any time since the collapse of the copper corner. Some difficulty is said to have arisen in inducing the American mine owners to consent to a prolongation of the restricted output arrangement, so that the rise in the price of copper may not continue. Bar copper rose from £43 to £44 per ton during May.

The Electrolysis of Water-Pipes.—A peculiar accident occurred a few days ago at the power-house of the West Side Railway Company, says the Milwaukee correspondent of the *Western Electrician*. The water main in front of the power-house burst, filling the street with water. The submerged tracks, and the impossibility of getting water for the boiler, made it necessary to abandon the whole line. The break occurred at 8 o'clock in the evening, and it was 10 o'clock before the water could be turned off. It is alleged that the accident was due to the corrosion of the pipe by electricity escaping from the cables. The cable ran parallel to the pipe, and close to it.

Boiler Explosions.—It is satisfactory to discover, from a recent report of the Board of Trade on this subject, that "the results of the working of the Boiler Explosions Acts do not tend to show that careless management of boilers is on the increase. Although the total number of cases of all kinds dealt with is higher than in past years, it must be remembered that every year the requirements of the law as regards reporting explosions are becoming more widely known, and that, although the number of boilers in use is probably becoming greater in each succeeding year, the actual loss of life and the number of grave cases dealt with show no tendency to increase."

Night Navigation of the Suez Canal.—Nearly 91 per cent. of the vessels using the Suez Canal in 1892 pursued their journey uninterruptedly at night by using the electric light, the percentage in the three preceding years being 88·21, 83·56, and 71·74 respectively. The Suez Canal authorities have made it obligatory that, after October 1st next, vessels passing through the canal by night shall employ an apparatus for dividing the light of the projector into two divergent rays. Approaching vessels may, by this means, travel right up to each other without their respective helmsmen being blinded. The diverging apparatus which is to be used has been devised by one of the agents of the Company.

Compass Disturbances.—We hear that the Admiralty has directed that all warships fitted with 300 and 400 ampere dynamos are to be specially swung for the purpose of ascertaining the effect of the dynamos on the ships' compasses. The effect on all the compasses is to be noted, and a report forwarded to the Admiralty. The Lords of the Admiralty have decided to enforce a minimum distance between dynamos and compasses, depending on the size of the dynamo. In the light of the experiments that are now to take place it would be interesting to know the distances between the dynamos and compasses of three of Her Majesty's ships that are said to have recently been damaged by getting into positions at direct variance with the navigator's intentions.

Lightning Fatalities.—From every part of England, as well as from many distant countries, comes intelligence of thunderstorms, and of havoc wrought by lightning, which has been of almost unparalleled severity. A number of deaths have resulted. At Fort Westmoreland, in Ireland, a soldier was struck by a flash, which tore all his clothing from his body, burned his boots, shattered the toes of his feet, charred one side of his body, and blackened his face beyond recognition. At Lampeter (South Wales) the lightning took the skin off the backs of a flock of sheep, burnt the wool, and then earthed. Near Devizes four burning farmhouses could be seen at one time. Simultaneously with this electrical activity, it is interesting to note the usual fall in atmospheric temperature.

American Telephone Patents.—The American Bell Telephone Company and E. Berliner have filed their answer to the Bill lodged by the Government to annul the Berliner patent in the United States Circuit Court for the District of Massachusetts. The answer is a general denial of all the charges made in the Government complaint, and avers that due diligence was observed in the prosecution of the case in the Patent Office; that the patent was ready for issue as early as 1882, and would then have been issued, but for the action of Examiner Brown, who rejected all its claims and raised other objections, all of which could have been done before that date. The Bell Company also aver that in the applications for the Berliner patent, all due forms of law were observed, and that the Government cannot repudiate the acts of its own agents established by the laws creating the Patent Office.

The Influence of Magnetisation on Thermo-electric Force. M. Chassagny has a note in a recent number of *Comptes Rendus* on the influence of longitudinal magnetisation on the electromotive force of an iron-copper thermo-electric junction. Two couples were used, one being in the axis of a long magnetising helix, so joined together that they acted in opposite directions. The results obtained were:—(1) The effect of longitudinal magnetisation is always to increase the electromotive force. (2). This increase is independent of the direction of magnetisation. (3) For increasing fields the increase is, at first, very nearly proportional to the strength of the field,

Digitized by Google

and attains a maximum value of 6·1 microvolts for a field of 55 C.G.S. units. After this, it slowly decreases, till, for a field of 200 units, it is 3·2 microvolts.

Switzerland.—We are indebted to the *Schweizerische Bau-Zeitung* for the following interesting statistics relating to the increase of electrical work in Switzerland between the dates December 31, 1890, and December 31, 1892. The isolated plants and central stations had, at the end of last year, an aggregate output of 11,422 kilowatts, an increase of 64·5 per cent.; and the total plant capacity of all electrical installations has increased 34·7 per cent. Among the more notable features are four electric tramways, with overhead conductors; the use of 17 alternate-current motors, a distance of 8 kilometres from the station to furthest lamp, in the case of the Mabrack-Pfäffers-Ragaz alternate-current station; and a synchronous 100-H.P. motor at Chur; and two "drehstrom" transmissions at Spreitenbach and Bülach-Oerlikon, the former working at a pressure of 5,000 volts, over a line 17 kilometres long, the latter at 13,000 volts, over a line 19 kilometres long, the power transmitted being, respectively, about 900 and 450 H.P. The statistics, unfortunately, do not show to what extent waterfalls are used as a source of power.

Truth in Science.—In a letter to the *Engineer*, with regard to the ether, Dr. Oliver Lodge winds up a lengthy controversy that has been raging in the columns of our contemporary with the following remarks:—

All scientific men must agree that freedom of discussion and absence of dogmatism are the life-blood of science. There is a distinction to be drawn, however, between dogmatism and instruction. Before there can be rational discussion on any subject, the facts should be equally known by both sides; and, until this state of things is reached, instruction is more appropriate than discussion. It is, perhaps, difficult sometimes to know where one should end and the other begin. Most certainly the theory of light is not complete; and as to the theory of ether, it is hardly begun. The same may be said for the theory of matter, and for the theory of gravitation. But we do not therefore call "matter" a hypothesis, or doubt the fact of its gravitative attraction. Whatever be hereafter discovered about the cause of gravitation, the Newtonian laws of its action cannot be upset; they are true, though of course not the whole truth. So also with the wave theory of light; so far as it goes, it is true, and not likely to be upset by any discoveries of the future. The ultimate mechanism of light is, indeed, still unknown; the complete theory of light has yet to be made, but nevertheless it certainly consists of transverse waves in a medium; and the frequency and length of these waves are known with as great accuracy as the frequency of a tuning-fork and the length of a metre—I am not making random statements—and the complex facts of optics are explicable on the wave theory just as the facts of astronomy are explicable on the gravitation theory; but to call either the complete theory, or to pretend that any assertion yet made by man is the whole truth about anything, however apparently simple, that would be a procedure less than sane.

The Specific Heat of Carbon.—In a note in the *Comptes Rendus* for May 8th, M. Le Chatelier remarks that it may not be without interest, in connection with the recent experiments of MM. Moissan and Gautier on boron, to recall the fact that the specific heat of carbon can no more than that of boron be made to agree with the law of Dulong and Petit. Monckman has already pointed out that Weber's experiments do not, in connection with the variation of the specific heat of carbon, lead to a law tending asymptotically to a fixed value, as is usually asserted. On the contrary, these experiments indicate a continuous increase above 250°C. At 250°C. the law of variation undergoes a sudden change, and the same discontinuity is observable at this temperature in regard to all the other properties of carbon: electric conductivity, expansion, thermo-electric power. Recent experiments carried out by MM. Euchène and Biju-Duval, engineers to Paris Gas Company, place Monckman's interpretation beyond doubt. The numerous experiments of these engineers show, moreover, that the specific heat of graphite (retort carbon) increases from 250°C. to 1,000°C. in rigorous proportion to the temperature, and that the rate of increase is much higher than would seem to result from Weber's experiments. The atomic specific heat is given by the formulæ—

$$250° - 1{,}000° \quad . \quad . \quad . \quad . \quad c = 3{\cdot}54 + 0{\cdot}0246t.$$
$$0° - 250° \quad . \quad . \quad . \quad . \quad c = 1{\cdot}92 + 0{\cdot}0077t.$$

Street Telegraph Lines in Sydney.—Our Australian cousins follow in the steps of the Americans, even in the matter of street telegraph poles, but, unlike the Americans, the Australians do not appear to accept them as inevitable:—"The utter disregard usually borne by the powers that be to the architectural embellishment of cities under their governance," says the *Building and Engineering Journal*, "is strikingly shown in the suit of the Attorney-General *v.* E. Way and Co., of Sydney, instituted with a view to obtaining an injunction to restrain the defendants from permitting a verandah and parapet in front of their premises, in Pitt-street, to remain erected in such a manner as to interfere with the erection of telegraph wires along the street." The building in question, says our contemporary, was one of the most recent improvements to the streets architecture of Sydney. The awning and balcony were supported by pillars 19ft. high placed on the outer edge of the footpath, and a parapet about 2ft. high had been erected on the top, making the height from the ground about 21ft. It was complained that this parapet encroached upon the space occupied by certain telegraph wires. Our contemporary concludes by remarking, that "to the architects who are filled with laudable aspirations to create elegant forms and beauty-spots in Sydney, or ornament their structures, this decision comes as a strong warning not to depart from the stereotyped manner of doing as their fore fathers have done, which will, no doubt, bear meet fruit."

Glasgow Philosophical Society.—At the concluding meeting of the Session of the Glasgow Philosophical Society last week, Dr. J. T. Bottomley made three communications on subjects of public interest. Dr. Bottomley's first communication was on "Vacuum Tubes without Electrodes." In 1881 Dr. Bottomley showed to the Philosophical Society for the first time vacuum tubes which he had just then constructed, and which had no electrodes of any kind—that is, no conducting wires by means of which electricity can pass in or out through the non-conducting glass walls of the tube. On the present occasion all the phenomena of striation and of attraction and repulsion of the discharge by currents outside the tubes were shown within these tubes, in spite of the fact that the electrodes did not exist. Tubes containing pieces of Iceland spar was also exhibited, the crystals being illuminated by the molecular bombardment of the minute traces of gases still existing in the vacuum. It was shown that the phenomena are highly complicated with the mixed effects of current induction and of electrostatic induction; and that the electrostatic disturbance of the vacuum has not been sufficiently taken into account in attempts to explain the phenomena. The second Paper Dr. Bottomley contributed was on "Some Results of Instantaneous Photography," in the course of which he showed and explained many interesting photographs of flying bullets, for which he was indebted to Prof. Boys. Dr. Bottomley, in his third communication, exhibited and described a portable apparatus for "Testing the Insulation of Electric Light Wires." He explained that this matter was of great interest and of special importance, now that the electric light was being introduced into Glasgow for lighting streets and dwelling-houses. The instruments hitherto designed and offered for testing the insulation of houses and mains had been found by Dr. Bottomley to be very unsatisfactory, defective and costly, and he exhibited an improved apparatus for this purpose. He advocated very strongly the use of a very sensitive high-resistance galvanometer with proportional graduation, and a direct comparison between the insulation of the installation to be tested with high resistances prepared for the purpose. The galvanometer shown was a modification of Lord Kelvin's well-known tangent galvanometer used in his graded galvanometers. It was of such sensibility as to give a deflection of one scale division per millionth of an ampere, the magnitude of the division being such that one-tenth of a division was easily readable. The resistance of the galvanometer was 22,000 ohms. While testing with an electromotive force of 100 volts it was easy to exactly determine any insulation up to 150 megohms. The insulation expected in ordinary buildings might be from 10 megohms down to 200,000 ohms, according to the number of lights installed. Dr. Bottomley also exhibited resistances of a megohm (one million ohms) down to 100,000 ohms, and a portable bichromate battery constructed of minute test-tubes carefully insulated in paraffin, with small carbon rods and zinc wire.

ALTERNATE-CURRENT TRANSFORMERS.*

BY W. E. SUMPNER, D.SC.

An alternating current traversing a coil provided with an iron core has to overcome the back electromotive force caused by the changing induction in the iron. When the magnetic circuit is good, the back voltage due to the core becomes, with ordinary frequencies, so nearly equal to the forward voltage applied to the coil that the resulting current is generally less than one-twentieth, and may even be less than one-thousandth part, of the current obtained by dividing the impressed voltage by the resistance of the coil. The voltage needed for overcoming the mere resistance of the coil is negligibly small compared with that needed to balance the self-induced electromotive force due to the changing magnetism in the core, and it thus happens that the electromotive force generated in *any* turn of wire surrounding the core depends on the number of turns of the primary coil and the voltage applied to it, but does not depend to any appreciable extent on the resistance of the primary or on the current flowing through it. A secondary coil wound with a suitable number of turns is capable of supplying a variable current at a very approximately constant potential, provided the voltage at the terminals of the primary be maintained constant.

In designing a transformer the following objects have to be kept in view :—The losses in the transformer should be reduced to a minimum, and especially those occurring on open circuit. The regulation should be good, *i.e.*, when the primary coil is supplied at a constant potential the drop of volts on the secondary, as the load is increased, must be small. The current on open circuit should be small to reduce waste in the leads. The construction should be cheap and durable, and the coils and core so arranged that the transformer may be easily taken to pieces for repairs. The weight should be as small as possible, consistent with the provision of enough radiating surface to keep the transformer cool.

Magnetic Circuit.

All the early transformers were of the *open circuit* type, the lines of force produced by the currents in the coils circulating partly through an iron core and partly through air; but it has since become the all but universal practice to make *closed circuit* transformers, the path of the lines of force being entirely through iron. In all cases the iron core must be well laminated in the direction of the lines of force to reduce loss of energy in eddy currents.

Losses due to Hysteresis.

If the magnetism of a piece of iron is changed in any regular way, a definite amount of energy is absorbed by it each time the change occurs This loss is said to be due to hysteresis, and our knowledge of its amount is mainly due to the researches of Prof. Ewing. It has been shown by Mr. C. P. Steinmitz that Ewing's results may be summarised in the following law :—

$$h = \eta \, \mathbf{B}^{1.6},$$

where h is the loss of energy in ergs in every cubic centimetre of iron for every double reversal of magnetism, the maximum induction density being $\mathbf{B}$ lines of force in C.G.S. units per square centimetre. η is a coefficient, the value of which depends on the quality of the iron. Ewing's results for very soft iron correspond with the value $\eta = 0{\cdot}002$. The value of η seems to depend much less upon the chemical constitution of the iron sample than upon its physical condition. Annealing decreases and hardening increases the hysteresis very considerably. The purer the iron the lower the value of η.

There is good experimental evidence† to show that the loss in hysteresis in any magnetic cycle does not depend upon the speed with which the magnetic changes take place, even if the frequency varies from 1 ∿ (period per second) to 150 ∿ (150 periods per second). Messrs. Evershed and Vignoles find that when tests are made *very slowly* the influence of magnetic lag is to diminish the hysteresis, sometimes by as much as 20 per cent. The value of η found by slow methods may thus have to be increased to this extent to render it applicable to transformers. This difference is, however, smaller than that often found between various samples of iron of the same manufacture. The value of η for the iron usually employed in transformers cannot be taken lower than 0·0025; a greater value is more probable, as the handling of the iron during manufacture hardens it and increases η For this reason it is advisable to carefully anneal the core-plates after punching.

If W_h is the loss of power in watts occurring in the core of a transformer due to hysteresis

$$W_h = \eta \, n \, \mathbf{B}^{1.6} \, U \times 10^{-7},$$

where U is the volume of the iron in cubic centimetres, $\mathbf{B}$ is the maximum induction density in C.G.S. lines per square centimetre, η is Steinmetz's coefficient, and n is the frequency of the current.

Losses due to Eddy Currents.

If v be the number of volts (mean) induced in any single turn of wire enclosing the magnetic circuit

$$v = 4{\cdot}45 \, S \, \mathbf{B} n \, 10^{-8},$$

where S is the area in square centimetres of the section of the magnetic circuit; also

$$V_1 = n_1 \, v, \qquad V_2 = n_2, \, v,$$

where n_1 and n_2 are respectively the number of primary and secondary windings, and V_1 and V_2 are the primary and secondary voltages.

If the core consists of m iron wires of circular section, the specific resistance of the iron being ρ, and the length of the magnetic circuit l centimetres, the number of watts W_e, lost in eddy currents is

$$W_e = \frac{v^2 \, l}{25 \, m \, \rho}.$$

Usually the core consists of a large number of thin plates of rectangular section. If there are m of these plates in the core, and if the section of each plate is m' times as long as it is thick

$$W_e = \frac{v^2 \, l}{a \, m \, m' \, \rho},$$

where a is a number which varies between 10 and 30, according to the value of m'. In ordinary transformers m' is very large, and $a = 12$ is the most probable number. The value of ρ for transformer plates may be taken as 13×10^{-6} at ordinary temperatures (Evershed). It increases by nearly half per cent. for every degree centigrade.

If t is the thickness of the core plates, in millimetres, $m \, m' \, t^2 \, 10^{-2} = S$, the section of the iron of the core (in square centimetres) we get by substitution and reduction

$$W_e = 64 \frac{v^2 \, t^2 \, l}{S} = l \, S \left(\frac{8 \, v \, t}{S} \right)^2.$$

The number of watts wasted in each cubic centimetre of the core by eddy currents thus equals

$$\left(\frac{8 \, v \, t}{S} \right)^2,$$

a quantity for which Dr. Fleming has given the formula $[n \, t \, \mathbf{B} \, 10^{-8}]^2$, where t is the thickness of the plates in English *mils*.

The thickness t should not exceed 0·5 mm., and the general practice is to use plates slightly thinner. If t exceeds half a millimetre, it has been shown by Profs. J. J. Thomson and Ewing that the eddy currents disturb the distribution of the lines of force in the core, that the losses caused by hysteresis are greater than the formulæ given above imply, and that the eddy current losses become excessive. With the values of t usually found in transformers, this disturbance is inappreciable. In order to avoid eddy currents flowing from one plate to the next, it is usual to insulate adjacent plates by means of a coat of shellac, or the interposition of thin varnished paper.

This freedom from eddy currents is sometimes attained by the oxidation of the surface of the plates resulting from a special steaming process.

Losses in Resistance.

The average value in amperes of the current (in the primary of n_1 turns) needed to magnetise the core to a maximum induction $\mathbf{B}$ is very approximately

$$A_m = \frac{l \mathbf{B}^{\frac{1}{3}}}{10\, n_1},$$

where l is the mean length of the (closed) magnetic circuit (in centimetres). This formula follows from Dr. Fleming's formula for permeability,

$$\mu = 5{\cdot}6\, \mathbf{B}^{\frac{2}{3}},$$

which is reliable for values of $\mathbf{B}$ lying between 1,000 and 6,000. Formerly transformers were frequently worked with a higher value of $\mathbf{B}$ than 6,000, but general practice now favours much lower values. The actual open circuit current will be greater than A_m, owing to the loss of energy in the core, the increase of current is

$$\frac{W_h + W_e}{V_1}.$$

If W be the load in watts taken from the secondary coil at voltage V_2, the secondary current is $A_2 = W/V_2$, and the primary current at this load is

$$\sqrt{A_1^2 + A_m^2}, \text{ where } A_1 V_1 = W + W_h + W_e$$

The loss of power in the coils at this load is

$$W_c = (A_1^2 + A_m^2) r_1 + A_2^2 r_2,$$

where r_1 and r_2 are the resistances of the primary and secondary coils. This loss is expressed as a fall of voltage at the secondary terminals. The drop of voltage bears the same ratio to the voltage V_2 on open circuit that W_c bears to W. This ratio for good regulation should not exceed 2 per cent., and should be equally divided between the two coils of the transformer. Equality between the copper losses in the two coils can be secured by choosing such gauges in winding that the weight of copper in the primary coil is practically equal to that in the secondary. The insulation of the coils increases the space they occupy by fully 50 per cent. for the primary (thin) coil, and by about 10 per cent. for the secondary. To avoid eddy currents in the copper it is advisable to strand the secondary, but the use of strip or square section solid conductors is common. If the secondary consists of two coils put in parallel, the two conductors should be wound on together. The current density in the coils at full load varies with different makers of transformers. It frequently lies between 700 and 1,000 amperes per square inch.

Efficiency.

The efficiency of a transformer expressed as a percentage is

$$100 \left\{ 1 - \frac{W_h + W_e + W_c}{W + W_h + W_e + W_c} \right\}.$$

The weight of experimental evidence confirms the theoretical conclusion that the core losses, $W_h + W_e$, are constant under all conditions of load. It follows from this and from the facts that W_c varies as the square of the current, and W as its first power, that the efficiency of any transformer will be greatest when the load is such that

$$W_c = W_h + W_e,$$

or when the iron losses equal the copper losses. But this consideration alone does not determine the best load. To keep the transformer cool, a radiating surface of from 3 to 4 square inches per watt is required. A transformer in practice is often run for a great part of its time on a light load, and to secure the highest average efficiency the iron losses should be diminished at the exense of those occurring in the copper. To secure good regulation, the ratio of W_c to W should not exceed 2 per cent.; and with small transformers, which cannot be made as efficient as large ones, this consideration is the chief one needing attention.

LUMINOSITY IN VACUUM TUBES.

BY E. C. RIMINGTON.

The remarks made in the Editorial Notes of May 5, 1893, on my Paper before the Physical Society, on "Luminous Discharges in Electrodeless Vacuum Tubes," lead me to think that a short article on the subject of the cause of luminosity in vacuum tubes would be of general interest.

Take first the case of a uniform electric field between two flat plates (A and B, Fig. 1), to fix our ideas definitely. Introduce into this a cylinder of dielectric *a*, *b*. If this cylinder be composed of a dielectric of the same specific inductive capacity as that between the plates (presumably air), it will make no difference in the distribution of the lines of induction, if however, its specific inductive capacity be greater than air, as it would be if the cylinder were glass, ebonite, paraffin wax, or gutta-percha; for example, the effect of introducing it into the field will be to make the lines of induction crowd into it and pass through it; but it will produce no other effect. Suppose, now, this cylinder to become ever so slightly conducting, the lines inside it will collapse, their rate of collapse depending on the conductivity of the cylinder, and finally we shall have some of the lines starting from A, terminating at *a*, an equal number starting from *b* and terminating on B. On putting it in the ordinary artificial language of the text-book, *a b* will be electrified by induction, and there will be a negative charge at *a* and an equal positive charge at *b*. During the time taken for the first state to change to the second, there will be a current in the cylinder from *a* to *b*. If the cylinder were a good conductor the time taken for this change would be infinitesimally small, as the electric stress which exists in the cylinder when it is a dielectric and non-conductor, breaks down almost instantaneously in the case of a conductor.

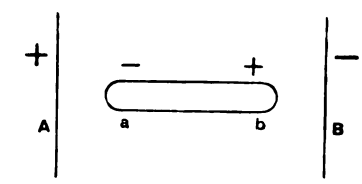

FIG. 1.

If the electric field between the plates A and B be made to vanish by connecting them together through a conductor, the lines terminating on and emerging from the cylinder will again pass momentarily through it, or in the artificial (but convenient) mode of expressing what happens, the + charge at *b* will reunite with the − charge at *a*, and there will thus be a current in the cylinder from *b* to *a*. Instead of discharging A and B, the cylinder may be removed out of the field, and practically the result will be the same. As regards the current in the cylinder (supposing it a conductor) its strength will depend on the rate at which the cylinder is put into or taken out of the field; the quantity of electricity passing will, however, be the same, whatever the rate. The energy dissipated by the cylinder will be greater the greater the maximum value of the current, that is, the greater the rate at which the cylinder is put into or taken out of the field, or if the cylinder is stationary, the greater the rate at which the field changes.

Let us now consider how a glass tube containing a rarefied gas will act when placed in the electric field. Air or any other gas acts as a dielectric, and is capable of having an electric stress set up in it; when, however, this stress exceeds a certain value, depending on the rarefaction of the gas, the gas gives way and becomes for the moment practically a conductor, allowing the lines of induction through it to collapse. This takes place even at ordinary atmospheric pressure when the electric stress is great enough, it is commonly known under the name of "brush discharge." It is best shown by an experiment described by Mr. J. E. Taylor in the *Electrical Review*, July 31, 1891; two clean and dry glass plates have a piece of tinfoil pasted on one side. They are then placed parallel to one another with their uncoated sides nearest each other and separated by an air space of about $\frac{1}{4}$ of an inch On connecting the tinfoil plates to the poles of a Wimshurst machine and

Digitized by Google

looking between the plates, the break-down of the strain in the inner air space can be plainly seen in the form of sparks and brush discharges.

When it is said that the air or gas becomes practically a conductor, it must be understood that it does not conduct in the same manner as a piece of metal, but rather convectively, much after the manner of an electrolyte or of a lot of pith balls placed between two charged plates, the dissociated atoms * present playing the part of the pith balls.

To return to the exhausted tube; suppose it placed between the plates A and B, as in Fig. 1. The lines of induction pass through it, and if the electric stress be sufficient the rarefied gas will give way and the tube behave as if it were the conducting cylinder previously considered. While the lines passing through the tube are collapsing there will be a convection current flowing in the tube. During this collapse of the lines the molecules of gas in the tube will be in a state of more rapid vibration than corresponds to the temperature, and their collisions with each other will consequently be more violent; this will cause their own vibrations † to have more "overtones," as we may express it, by analogy with a sounding body. If these overtones be sufficiently developed we shall have the molecules capable of imparting to the ether surrounding them waves short enough to affect the retina of the eye, or the tube will appear luminous. To obtain luminosity it is necessary that the tube should be suddenly placed in, or withdrawn from, the electric field, so that the collapse of the electric stress may be sudden, as if it be at all gradual the increase in the vibrations of the molecules is not sufficient. This effect may be simply shown by holding a rubbed ebonite or glass rod close to an exhausted tube, and suddenly jerking it away; at the instant of doing this, a flash will be seen in the tube. The same thing will happen if the rod be suddenly brought up to the tube. Another way is to take a tube and place it flat on a silk or flannel rubber laid on the table, rub the tube on the silk, taking care that the whole of it is in contact with the latter, no luminosity will be visible; but, if the tube be suddenly lifted, there will be a luminous flash in it.

In the case of an ordinary Geissler tube, with electrodes attached to a battery of several hundred cells, there is an electric field set up in the tube between the electrodes, the rarefied gas gives way under the stress, producing luminosity; but the stress is immediately renewed by the battery, to again give way, and so on continuously as long as the battery is applied to the tube.

It is necessary, then, to produce luminosity in a vacuum tube of any sort that it shall be in an electric field (or have an electric field through it), which shall vary relatively to the tube; and, moreover, this variation must be sufficiently rapid. This can be done by placing the tube between two plates, which are alternately charged and discharged, or by jerking the tube rapidly into or out of the space between the plates, the charges on the latter being kept constant. (I have never succeeded in obtaining luminosity in this manner with plates, as I have been unable to jerk the tube quickly enough; but by jerking the tube away from the charged rod, previously described, luminosity is easily obtained.) Another way is to spin the tube about an axis at right angles to its length, between two charged plates, or near a charged ebonite rod, as described in a Paper on "Experiments in Electric and Magnetic Fields," by the author and Mr. Wythe Smith, and also in an article in this paper, March 24, 1893, entitled "A Novel Electroscope."

* The word atom is here employed in the chemical sense, as there seems to be a balance of evidence in favour of the fact that the molecules of a gas are incapable of receiving or giving up electric charges. In the case of an exhausted tube there will always exist a certain number of free atoms due to dissociation of some of the molecules; the number of these dissociated atoms appears to be increased on passing a discharge through the tube. This increase is sub-permanent. One proof of this is that if a freshly exhausted tube be taken it is insensitive, as far as luminous effects are concerned, to change in electric stress that is not above a certain value, as, for example, spinning it near a charged body; if, then, it is made to experience considerable change of electric stress as by allowing a Wimshurst machine to spark on to it, it will be found to be sensitive to the smaller change of stress which was previously too small to effect it. After being put aside for some months it again becomes insensitive.

† More probably the surgings of the charges of the atoms composing them.

Again, another method of producing electric stress in an exhausted tube or bulb is by having lines of magnetic induction passing through the bulb and rapidly varying their number and direction. This will give rise to closed circuits of electric stress within the bulb in planes normal to the direction of the magnetic induction. This effect is obtained by holding an exhausted tube close to a wire through which a Leyden jar is discharged, or by surrounding the tube with this wire. The electric stress in the tube will be greatest close to the wire, where the magnetic induction is strongest, and the breakdown of the gas will be most violent where the electric stress is the strongest, so that there will be a brilliant luminosity close to the wire. The rest of the closed path of the electric stress will be a more diffused and much feebler luminosity, which easily passes unnoticed by a casual observer, being swamped by the much brighter luminosity close to the wire. Fig. 2 shows practically what takes place. A B is the wire through which the Leyden jar is discharged, C E D the brilliant luminosity close to the wire, while the dotted lines C F D show the diffused luminosity forming the closed path.

It must be clearly borne in mind that these electromagnetic discharges, as they may be termed, are just as much produced by electrotatic stress acting in the rarefied gas, and under which it gives way, as in the case of a vacuum tube placed in a varying electric field, before considered. There is this difference, however, but it is quite a minor one, that in the former case the lines of electric stress are closed curves within the tube; in the latter they are not closed within the tube. It is simply in the cause of this electric stress that the two differ from one another, in one the electric stress being caused by bringing the tube into an electric field existing between or near to charged conductors; in the other it is caused by the varying of magnetic induction. In the case of a bulb surrounded by a

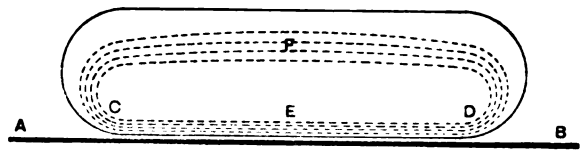

FIG. 2.

coil of one or more turns of wire connected to the outer coatings of two Leyden jars, there will be electric stress in the bulb due to the two causes, the one being due to the potential difference between different parts of the wire, and the other to the alternating current in the wire. Needless to say, these two stresses do not act in the same direction through the bulb; the first will act more or less from side to side, and if acting by itself would produce a faint luminosity filling the whole bulb; the second acts in a closed path following the wire, and produces a closed luminous band. The effect of the first may be much increased by connecting a conductor near to, or in contact with, some part of the bulb, to one of the outer coatings of the Leyden jars. I cannot agree with the remark made in the Editorial Note above referred to, that "where these two effects are mixed it is very difficult to follow the actions." I venture to think that the series of experiments described in my Paper before the Physical Society on "Luminous Discharges in Electrodeless Vacuum Tubes" pretty clearly shows the part played by the two effects in producing luminosity, and to that Paper (*Phil. Mag.*, June, 1893) I would refer the reader, who may desire fuller information on this subject. I may remark that all the experiments given in the first part of that Paper must be considered together, and as only one or two are given in the abstract of it published in *The Electrician* of May 5th, the argument cannot be followed from it.

An Electric Welding Car.—A special electric welding car has been constructed at Philadelphia for welding the rails of street railways in position. The car is provided with an electric welding plant, so constructed that current is taken from the trolley wire and transformed into a low-tension current of desired strength. The time taken is from four to sixteen minutes for a complete weld.

INSTRUMENT FOR TESTING PRIMARY BATTERIES.

An instrument, which should prove of great service for testing the condition of a primary cell, has been designed by Major Holden, and was exhibited at a *conversazione* of the Royal Society. A small wooden case measuring 3½in. by 4½in. by 2in. deep, contains a dead beat voltmeter reading from 0·5 to 1·5 volt, and a resistance coil. The instrument, which is made by Mr. Pitkin, is shown in Fig. 1 with the outer case removed. The voltmeter *a* is constructed on the principle common to other Holden instruments, and briefly described in *The Electrician*, Vol. XXIX., p. 589. A club-footed magnet, or a horseshoe magnet, having one coil is used. The limb within the coil is circular, the outer one being flat, lying against the coil, the end projecting a little. The circular limb carries a small radial pole-piece. A jewelled arbor is mounted as an extension of the axis of the coil, and carries a soft iron radial needle; the end is tipped with brass to prevent magnetic contact. The action of the peculiar magnetic arrangement causes the iron needle to be repelled from the radial pole-piece when a feeble current passes, but when it has moved through an angle of some 10deg. the other pole of the magnetic system begins to attract it. As a result, a fairly uniform scale is obtained. A spring control is employed, which allows the instrument to be held in the hand and used in any position. A resistance coil, *b*, is provided, and a push-button, not shown in the illustration, acting on the spring-contacts *c*, reduces the resistance from 8 ohms to 2 ohms.

The method of using the instrument is as follows:—Two short, thick wires having been connected to the terminals terminating in ends or in a suitable double pointed spear, the ends or spear are put in contact with the poles of the cell it is desired to test; this gives one reading, viz., the difference of potential at the terminals of the cell when it is working through an external resistance of eight ohms (neglecting the resistance of the leads). Then by pressing the push in the side of the case another reading is obtained, this latter being the difference of potential at the terminals when the cell is working through two ohms external resistance; from these two readings (which should be taken as quickly as possible) the electromotive force and internal resistance can be calculated, or their values can be got by reference to a table. The following are the results of a few tests with well-known cells:—

	First reading.	Second reading.	E.M.F.	I.R.
1. Leclanché 6-block agglomerate round pattern (condition, very old)	1·32	1·22	1·35	0·22
2. Leclanché's porous pot pattern, 3-pint size (condition, new)	1·4	1·21	1·47	0·42
3. E. C. C. dry cell, special firing pattern, weight 6·25lb. (condition, new) ...	1·43	1·38	1·96	0·15
4. Leclanché Barbier dry cell, No. 1 size (condition, fair)	1·3	1·05	1·43	0·68

The methods of ascertaining the electromotive force and internal resistance of a battery are well known, and possibly the following graphical construction is not new, but it is well worthy of attention, being a singularly neat example of graphical calculation. On a piece of squared paper a scale from 0 to 8 is laid down from right to left, and on this is set off the external resistances of the instrument. On the same line, and with the same values of scale divisions, the internal resistance of the battery is to be measured. A vertical scale is chosen to give convenient angles in the construction of the diagram, and on it is set off the volts measured by the instrument. Straight lines are drawn from the 8 and from the 2 on scale of resistances through the readings on the vertical scale, and meet at a point on the right-hand side of the zero resistance. The horizontal distance of this point from the zero line gives the internal resistance. The height of this point measured on the vertical scale gives the true electromotive force of the battery. Figs. 2 and 3 relate to the second and third examples already given.

The possible element of error in such a method of testing as that upon which this instrument is based is, of course, that, owing to polarisation, the volts of the cell when circuited through the two ohms may be lower than its previous value when circuited through eight ohms, and that both of them will be lower than the volts on open circuit. The error is reduced to a negligible quantity by making the test quickly, and by preventing very large currents from passing through the cell;

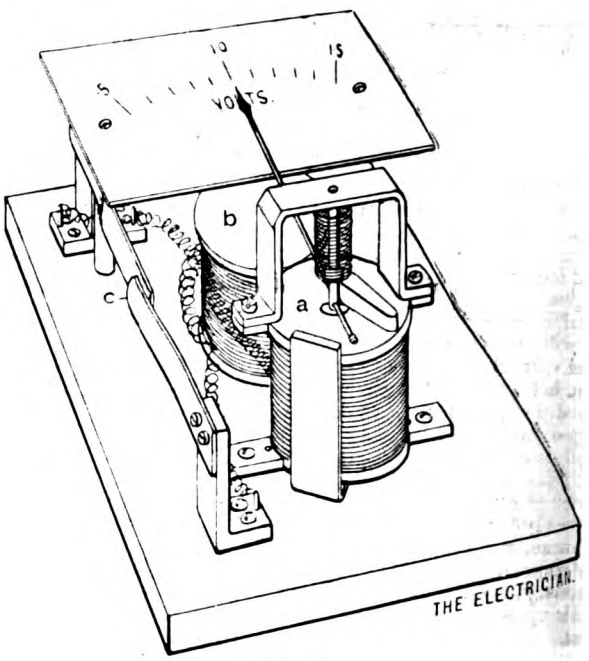

FIG. 1.

but for the second precaution high resistances are necessary, and these are objectionable because of their great disproportion to the magnitude of the internal resistance which is to be measured.

RAIL BONDING.*

BY C. W. WASON.

This matter of rail bonding is very vital to the interests of street railroads. I am confident that this important branch of the electrical equipment has not been given sufficient attention. I am convinced that a metallic return circuit of equal capacity to overhead feeders must be provided, and that care and attention must be given to the joints in order to reduce resistance and make the metallic circuit perfect in itself.

I will explain and illustrate to you what I consider the best rail bond. In the centre of the rail, that is, longitudinally, I drill a $\frac{17}{32}$in. hole, about 2in. or 3in. from the bottom of the rail. When placed in position on the track on the ties, this hole is then tapped out with a $\frac{5}{8}$in. taper tap. At the shop we prepare a rail bond, one end of which is soldered into a terminal of brass about $\frac{5}{8}$in. thick and 1$\frac{1}{4}$in. diameter with a $\frac{5}{8}$in. hole through. This is tinned carefully all over, and then a galvanised bolt is screwed into the newly-tapped hole through the hole in the terminal; the threads, of course, will fit it, and being tapered, the bolt will be screwed home and make a fairly tight joint even without any solder, if that be necessary. The bolt comes through about one-sixteenth of an inch, and is upset to further insure against the probability of its working loose. One reason for not putting the rail bond at either end of the rail, as has commonly been done, is that the rail will give or spring at the end. Then, again, one rail bond is sufficient to each rail, and only one hole is necessary in each rail. After the nut is set up tight the joint is painted with shellac, covering the bolt and terminal and the wire for a short distance out, say 3in. or 4in. After that has dried two coats of asphalte varnish are applied. The reason for putting on the shellac is that the asphalte varnish does not seem to cling to the iron as well as the shellac does.

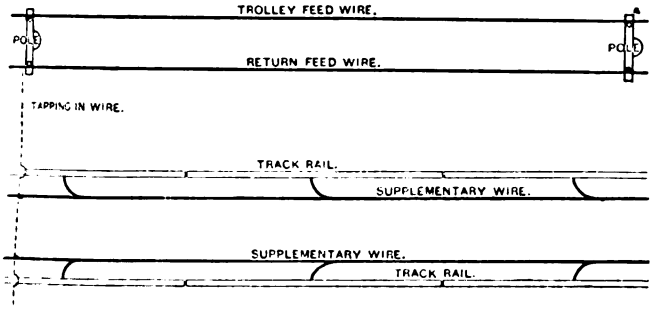

Diagram of Mr. Wason's Method of Rail Bonding, and Return Feeder Connection.

I have drawn a diagram which will possibly illustrate my idea of track wiring. We will call from the left to the right of this sketch 500ft. The rails you see are attached to the ground wire in the centre of each, in the manner I have shown, and at each 500ft. a No. 0 copper wire is connected to each of the four ground wires, or supplementary wires, and run to the pole on the side of the street. It is better if this wire is laid in a box filled with asphalte and run through a pipe which is also filled with asphalte up to the pole. These connections run up at about every 500ft.; they may end there for the present. Heretofore, as the traffic increases on the electric road, an additional feed wire is run out, and in six months or a year another one is run out. Nothing is done with the underground wiring; that remains the same as it was when started. As a matter of fact, it is getting worse and worse each year, and still nothing has been done to re-enforce it. My idea is, as you add feeders, to add return wires and connect these number 0 wires which have been run up the pole when the track was laid. In that way you have got enough copper and metal in the ground to take care of any possible amount of current that you will need to take care of between these 500 foot points. If you fill that track full of cars and started them all at once, which is, of course, a very improbable and almost an impossible condition, you will still have enough metal to carry the current required. Then by having your feeders proportionately large you will relieve the heating and burning out of joints that might be otherwise overloaded.

I think the entire system should be quite independent of the earth for its return circuit; that a return circuit should be provided with copper equal to that which distributes, if you can use these terms.

* Abstract of a Paper read before the Electric Club of Cleveland.

ON THE DISSIPATION OF ENERGY IN A ROTATING ELECTRIC FIELD, AND ON ELECTROSTATIC HYSTERESIS.*

BY RICCARDO ARNÒ.

In a preceding Paper (*The Electrician*, Vol. XXX., p. 516, March 3, 1893), Signor Arnò described a method for producing a rotating electric field by means of a simple alternating difference of potential between two fixed points. This was made, by the interposition of a high resistance and a condenser, to produce two superimposed electric fields, both of them alternating, but the one lagging a quarter-period behind the other, thus producing a continuous rotation of the resultant. A dielectric cylinder suspended in this field was found to follow the rotation of the field itself, a phenomenon which the author attributed to a species of hysteresis in the dielectric analogous to magnetic hysteresis. Since then M. Hess has propounded the theory (see *La Lumière Electrique*, November 26 and December 10, 1892, also *The Electrician*, Vol. XXX., p. 518, March 3, 1893), that the heating of a diele tric substance under the influence of an alternating electrostatic field is due, in part at least, to the presence of conducting particles disseminated throughout the dielectric. Herr Steinmetz (*Elektrotechnische Zeitschrift*, April 29, 1892, also *The Electrician*, Vol. XXVIII., p. 602, April 8, 1892), on the other hand, measured the energy transformed into heat in the conducting layers of a paraffined-paper condenser, and found it proportional to the square of the effective difference of potential. This transformation he attributed to hysteresis in the dielectric layers

The present note was written with the object of describing an apparatus which utilises the rotation of a dielectric cylinder in a rotating electric field for the study of electrostatic hysteresis, and to place on record some results obtained with this apparatus in the case of an ebonite cylinder.

A small hollow cylinder of ebonite was hung by a bifilar suspension between four plates of copper, arranged in a circle and facing inwards, which served to produce the rotating field. A piece of aluminium wire, attached to the ebonite, carried a small mirror, and also a closed hollow cylinder of electrolytic copper, suspended between the poles of a horse-shoe magnet, to render the arrangement dead-beat. The whole was enclosed with a disc of calcic chloride in a metal case connected to earth. The energy consumed while the apparatus was at work was measured on the principle of the friction dynamometer, by the steady deflection produced by a certain rate of rotation. This was done for effective differences of potential varying from 5 to 18 volts, as measured by a Cardew voltmeter. The intensity of the field, calculated from the distance between the copper plates, and the difference of potential between the ends of the secondary coil of the induction coil, as shown by a Thomson electrostatic voltmeter, ranged from 0·95 to 3·33 electrostatic C.-G.-S. units. On plotting the logarithms of the differences of potential (as abscissæ) and those of the corresponding deflections (as ordinates) the curve obtained was sensibly a straight line, showing the law connecting the two to be of the form

$$\log d = \log h + x \log v,$$

where d is the deflection, v the potential difference, and h a constant. Hence this notation could be written

$$d = h\, v^x,$$

or in terms of W the energy absorbed, F the intensity of the field, H another constant, and $x = 1{\cdot}607$, as found by a series of fourteen determinations,

$$W = H\, F^{1{\cdot}6}.$$

In this formula, the exponent of F differs from that required by Hess's theory of conducting particles, and tends to confirm the hypothesis of the dissipation being due to hysteresis.†

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

FRIDAY, June 23rd.

PHYSICAL SOCIETY.

5 p.m. Papers to be read: (1) "Exhibition of a Form of Carey-Foster Bridge," by Mr. Nalder; (2) "An Influence Machine," by Mr. Pidgeon; (3) "An Influence Machine," by Mr. Wimshurst; (4) "A New Volumenometer," by Mr. Myers.

INSTITUTION OF ELECTRICAL ENGINEERS.

9 p.m. Conversazione at the Institute of Painters in Water Colours, Piccadilly.

ELECTRICITY SUPPLY IN LONDON.

Our analysis of the accounts of the electricity supply companies of London needs less introduction than last year. We have as before taken the Board of Trade forms of accounts and these alone as our basis, and these, as far as they go, enable us to bring all the figures into uniformity. It is to be regretted, perhaps, that no provision was made in the original model form of those accounts for a statement of the actual output of each company. With but one exception, the companies have furnished us with their outputs as metered out of the stations, and these form together an aggregate of 7,915,746 units, as against about 4,300,000 of last year. This increase of about 84 per cent., compared with the small extension of mains during the year, is highly satisfactory. The total receipts have risen from £143,992 to £225,790 ; this is an increase of 57 per cent.; we are not, however, immediately concerned with the financial result or with the price of shares. There is no end to the analyses which *might* be made of the accounts, but we have confined ourselves to our original tables. The least satisfactory columns from the point of view of uniformity are those relating to distribution expenses. In considering these we have only followed the figures of the Board of Trade accounts ; but it is evident that different companies have different ideas on the subject. It is a pity that these were not more clearly defined at first. The St. James' and Pall Mall Company solves the difficulty by declining to separate distribution from generation ; the Westminster Company, who adopted this course last year, have now conformed to the Board of Trade model. The City of London Company has only six months' working to show, and has therefore been omitted.

Digitized by Google

Turning to the cost of coal per unit supplied, we find that the companies range themselves in the following order:—

Supply Companies in order of consumption of coal per Board of Trade unit supplied.

	d.
London Electric	2·36
House-to-House	2·1
Electricity Supply (Charing Cross)	1·91
Metropolitan	1·8
Chelsea	1·7
St. Pancras	1·665
Notting Hill	1·355
Westminster	1·047
St. James' and Pall Mall	0·945
Kensington and Knightsbridge	0·92

This table of coal consumption divided itself last year with great simplicity into those above 2d. and those below 2d. The former were all the alternating-current systems, and the latter, continuous-current, the Chelsea Company alone going into the wrong lobby with the alternate-current companies. Last year the House-to-House Company headed the list with 2·7d. per unit; this year, the London Electric Supply Corporation, for no very obvious reason, occupy this unenviable position. It must be remembered that this table is based on the coal-bill, and is not a record of the pounds of coal per unit. The London Company, which has increased its output by 81 per cent., unloads its coal at its own wharf, and one station, the smallest one of the Westminster Company, does the same. The London and the House-to-House Companies alone reach 2d. The simplicity of last year's order is marred by the interchange of position of an alternate-current company with a continuous-current concern. The Metropolitan Company has succeeded not only in getting below 2d., but below the Electricity Supply Company. There is, however, some doubt about the output of this latter Company; we have not succeeded in getting their actual metered output, and have had to deduce it from the revenue and the nominal price per unit. The actual output was, no doubt, greater, owing to contracts with theatres. Of the continuous-current systems, after the Electrical Supply Company, Chelsea is again the highest, but has succeeded in reducing the coal per unit from 2·22d. to 1·7d. Coming to the most economical companies, it is difficult to make strict comparisons. St. James' and Pall Mall are no longer in the proud position of the lowest coal consumption; they have lowered their figure from 1·05d. of last year to 0·94d., but the Kensington and Knightsbridge Company has left them behind, and is to be congratulated on 0·92d. per unit, almost one-half of the Metropolitan Company's figure. Prof. KENNEDY has nearly succeeded in running the Westminster Company for a pennyworth of coal per unit supplied. The statement of quantities generated, sold, used on works for lighting, meter-testing, charging batteries, and lost on feeders, is given with admirable clearness in the accounts of the Westminster Company. No less than 9·9 per cent. of the whole quantity generated was lost on the feeders, and only 1·41 per cent. is put down as having been expended on the batteries.

Two of the alternate-current companies are working at a disadvantage. The load of the London Company is altogether out of proportion to its plant, and the Metropolitan Company has two burdens, one at Whitehall and another at Rathbone place. The Sardinia-street station, while giving but little trouble and doing most of the work, cannot compete in economy with good English plant; and no company has so straggling a district, and probably none so many lightly loaded transformers. The last, however, is a palpable fault of the system, but one which can be remedied. Time will show in what direction alternate-current supply presents advantages for such crowded districts as those of the London companies, and to what extent sub-station transformers will improve matters. The alternate-current system is richly provided with mathematicians and electricians, but it seems to need an engineer of the CROMPTON or KENNEDY order to do justice on broad lines to the ingenuity of the details.

(*a*) This Company sets aside £4,348 to depreciation, redemption, and other charges. (*b*) £3,540 is set aside for depreciation and other charges. (*c*) This Company sets aside £4,000 to depreciation fund. (*d*) Includes distributing expenses, and £1,026 for maintenance of mains.

MR. DENNY LANE ON ELECTRIC LIGHTING.

(Concluded from page 184.)

The latest proposal is what is called "Thermal Storage," by which it is intended to store heat in the form of water, under very high-pressure, in strong wrought-iron vessels—in fact, auxiliary boilers without fires—which would be stocked with water heated by other ordinary boilers working all the 24 hours. This project has been devised by Mr. Druitt Halpin, and is spoken of rather favourably by Prof. Unwin. In the case of a central station, it is stated that at mid-winter 2,000 effective H.P. were required to meet the maximum demand, and ten large boilers should be provided; whereas, if the heat could be stored, three similar boilers working for 24 hours would bo sufficient. Mr. Halpin proposed to store the heat generated in the three active boilers in 24 wrought-iron vessels, 8ft. in diameter and 30ft. high, raising the temperature to 406° F. At the time when the thermal storage was partially exhausted, the temperature fell to 347deg., to be raised again to 406deg.; and it was calculated that, with this range of temperature, 16lb. of water would furnish 1lb. of steam at 130lb. absolute pressure. Taking 18lb. of steam per horse-power, we should, therefore, store up $18 \times 16 = 288$lb. of hot water at a temperature of 406° F., and a pressure of 265lb absolute, for each horse-power required. At present the ten boilers used cost £10,300; while three boilers and 24 high-pressure storage tanks would cost £15,000. But if by the arrangement ½lb. of coal per effective horse-power were spared, the annual saving would be 1,270 tons of coal. This shows the power consumption to be 5,689,600 H.P. hours a year, or 15,600 H.P. hours a day. Now if we divide this by 2,000 effective H.P. it would seem that, in mid-winter, the demand was equal to eight hours of the maximum capacity.

I may add that Mr. Halpin suggests that the waste heat heating the water in his storage tanks; and, taking the escaping from our retort-benches might be utilised for escaping furnace gases at 1,200° F., he estimates that the quantity of heat passing away into the chimneys of our gasworks would supply 30,000 effective horse-power night and day all the year round. But I think he must have taken our temperatures, and felt our pulses, before the regenerative system had been adopted; for, under such a system, no temperature so high as 1,200deg. reaches the chimney. At the same time, I believe that if the draught were not too much impeded some of the escaping heat might be picked up and utilised. Mr. Halpin estimated that it required 319lb. of coke to carbonise a ton of coal, or more than 14lb. per 100lb. of coal. This, of course, exceeds the quantity necessary in best modern settings.

To the complications and heavy initial expense of Mr. Halpin's system, some addition may be requisite on account of working for 24 hours instead of six or eight hours; but the proposal puts an additional grave accent over the already sufficiently grave difficulty of the load-factor.

Now the question arises, Is there any possible solution of this question? I answer at once that there is an easy and a ready solution; and that solution, gentlemen, is in *your* hands. Instead of storing chemical force in accumulators, water at a great elevation, or water at a very high-pressure, store *gas*, employ it in gas-engines, and the question is solved. Years ago I proposed this as the most economical system of supplying the electric light; and I was greatly gratified to find that so high an authority as Prof. Kennedy has lately recommended the same system to the Corporation of the City where we are now assembled. Let us see what capital will be required. For six months of the year, every well-designed gasworks has storage to spare; so that we have to provide additional gasholder-room for the winter only. Under ordinary circumstances, I suppose I may put down the cost of a gasholder at £12s. 10s. per 1,000 cubic feet; and charging 8 per cent. for interest and depreciation, this will come to about £1 a year. If filled and emptied 240 times a year, the cost of storage would be only 1d. per 1,000 cubic feet, or if filled 120 times—or, say, once a day for four months—the cost would be 2d. per 1,000 cubic feet. What will these 1,000 cubic feet do? At 25 cubic feet per effective horse-power, or 33⅓ft. per kilowatt, we get by means of a gas-engine 40 H.P., or 30 kilowatts, for a cost of 2d. for storage. So that, supposing you have to put up a new holder for the purpose, the outlay would be one-fifteenth of a penny for every Board of Trade unit. But I go further, and say that this storage costs less than nothing, if you take into account the cost of attendance on steam-engines, boilers, price of water, carriage of coal into and ashes out of a central station, and the cost of chimney shaft, setting, and repairs of boilers. But the heaviest loss is in the fuel wasted in getting up steam after several hours' rest of the boilers, and the waste of heat if the fires be banked for 20 hours out of the 24. On the other hand, the gas-engine can be started in a few seconds, and there is no waste in the "hours of idleness." Here, then, we have under our own hands the most effectual and cheap system for immediately supplying fuel when wanted, and restoring it in the frequently recurring intervals.

Having disposed of this difficulty, I come to another obstacle in the way of electric progress, viz., the cost of conductors. As long as overhead high-tension conductors were allowed, the difficulty was not so great. But since the Board of Trade nearly always requires undergound conductors, the cost has been greatly enhanced; and two systems have been adopted—for the low-tension system, bare copper rods laid in concrete culverts; and for both low and high-tension, insulated cables generally drawn through cast-iron pipes, which are sometimes filled with oil. Both of these modes are very expensive; and this has led to the transformer system, which is the most important development that has taken place during the last dozen years.

The transformers are of three totally different kinds, as they are to be used by the continuous or alternating current. In the first

(*e*) We were unable to obtain from this Company the total number of units supplied, and they have been calculated from the sale of current.

(*f*) Being a Local Authority no amount is set aside for rates and taxes.

case, the transformer consists of an electric motor made to revolve by the current; the same axis carrying a dynamo, the revolution of which in a magnetic field generates a current of lower voltage In the first step, the electricity is converted into motive-power, which is again converted back to electricity. The first may be a current of high-tension requiring a cheaper conductor; and the secondary current may be of the lower tension used in electric lighting. As in each of these conversions we get out (say) 86 per cent. of what we put in, the result is about $0{\cdot}86 \times 0{\cdot}86$, or under 57 per cent. of the originating current, without counting the loss in the primary main. For the low-tension system another plan has been used, viz.: four sets of storage cells are charged in series by an originating current of (say) 400 volts, until each set can give a tension of 100 volts. They are then disconnected from the charging mains, and discharged separately through the service mains at 100 volts. The object of the whole arrangement is to diminish the cost of the conductors in the ratio of over 3 to 1; but the heavy loss incurred by storage cells, their great cost, and rapid deterioration, are inseparable from this system.

As a motor actuated by an alternating-current has not yet come into practical use, another device has to be resorted to, the germ of which, as well as of those of many other inventions, is to be found in Faraday's earliest Papers on the subject. Taking a soft iron ring, he wound on different parts of it two coils of insulated copper wire. On making or breaking a battery current through one of these coils, a momentary current was produced in the other. The alternate-current transformer of the present day consists essentially of the same parts, viz., a soft iron core wound with two coils; one of thin wire through which the original alternating-current is carried, and the other of thicker wire through which a current of lower tension is generated fit for electric lighting. A common proportion is 2,000 volts reduced to 110 volts.

Now the only object of all these transformers is to diminish the cost of the conductors from the Central Station; and the relative cost of conductors depends on this principle. What the electrician sells is a watt; but the watt, like the foot-pound (to 44 of which it is equivalent), is a compound unit, being the product of the volt and the ampere. To secure a given product, we may make one factor very small by making the other very large—1lb. falling 1,000ft. is the equivalent of 1,000lb. falling one foot. Now the heating of the conductor, and the dissipation of energy as heat, in no way depends on the volts, but altogether on the amperes being proportional to the square of the amperes, multiplied by the resistance. Small wires offer more resistance than large ones; and to secure a sufficient number of watts through them, we must increase the volts and lessen the amperes, which alone cause the heating and loss of energy. The whole object, therefore, of these systems is to diminish the cost of the conductors; and it seems now to be generally agreed among practical men that it is not economical to send more than 1,000 amperes per sq. in. as the maximum current that a copper conductor can safely carry—a quantity which, at 100 volts, would supply about 750 16 c.p. lamps. But I find that Mr. Crompton, in his celebrated Paper on the relative efficiency of alternate-current and battery transformers, allows only 720 amperes per sq. in. Mr. Crompton says that a double conductor, each of $1\frac{1}{2}$ sq. in. section, shall be used for 1,080 amperes. At 110 volts, it requires about 7 amperes for a horse-power, so that the 3in. of copper gives only 154 H.P. It would, therefore, require two sets of these double conductors to deliver as much power as a 6in. gas-main could carry; and the cost, instead of £500 or £600, would now run up to £1,100. If the gas-pressure was increased to 16in. the corresponding electric conductors would cost £22,000. If the alternate current is employed, the insulated cables would, by Mr. Crompton's calculation, cost 2·63 times as much. Besides this, there would be considerable loss of electricity, and practically none of gas, in a main laid specially for the purpose, and not tapped for service-pipes.

But this change of tension cannot be effected without loss. My friend, Mr. Mordey, appears to have been very successful with the closed, while Mr. Swinburne advocates the open, Hedgehog transformer. What the loss is I would be afraid to say; but it used to be laid down that these transformers had a high efficiency when on a full load, but showed great loss at low loads. Originally each house was supplied with a separate transformer. Now, I believe, the transformers are "banked," using a large number, or those of large size, for the heavy hours, and a smaller number for the light hours. I must say I am rather surprised at the high yield claimed for some of them; and I should like to see some reliable return of the number of watts put into the main at the station and the number paid for by the consumer, for this is really the financial question to be settled. Dr. Fleming, who has devoted so much time and ability to this subject, estimates the efficiency of both forms open and closed throughout the 24 hours at 75 per cent. At Deptford they only hope for 70 per cent.—representing a truly formidable loss.

Is there any way of getting out of this difficulty about conductors? I allege there is; and again I say the remedy is in *your* hands. Instead of distributing electricity, distribute *gas* to be used in gas-engines near the spot where the electricity may be required. When, about a year and a half ago, I began to investigate the question seriously, I was surprised at the great economy of "distribution of energy by gas." Of course, it was only potential energy; and it would have been more correct to speak of the distribution of gaseous fuel.

The Editor of *The Electrician* was good enough in October, 1891, to publish a letter of mine on the subject, every statement of which has remained without contradiction. I took as an example a 6in. gas-main, which would not cost more than about £500 or £600 a mile. Such a main would, at a pressure of 4in., deliver at a dis-

Digitized by Google

tance of one mile 9,000 cubic feet of gas, which should yield 300 to 400 H.P. I showed that the power necessary to force the given quantity of gas at the given pressure was only one-tenth of a horse-power. I thus arrived at the result that we can send as much gas as will supply 3,000 to 4,000 H P. one mile for 1 H.P., costing ¾d. Of course, by raising the pressure to 16in., the delivery would be doubled, and the power quadrupled ; so that we could still send 6,000 H.P. one mile for 3d. This, I must say, is an extraordinary result, especially when you compare it with the efficiency of other modes of transfer of force so clearly explained by Mr. Kapp and Prof. Unwin.

Now let us take a glance at hydraulic transmission by a 6in. main, which, of course, for 750lb. pressure, must be far more expensive than a gas-main which has to bear only ½lb., or the 1,200th part of that in the hydraulic main. This expensive 6in. main will carry only 116 H.P., instead of the 600 H.P. which the cheaper gas-main can convey ; and while there is no appreciable loss on the gas-main, there is a loss of 20 per cent. on the hydraulic main. The cost per horse-power by high-pressure water may on an average be put down at 14d. for small, to 5d. for the largest powers, against ¾d. per horse-power for gas.

To revert to the question of storage, I may give Prof. Unwin's figures :—

The capital cost for storage of 1 H.P. hour is estimated by him as follows :—

Gas	£0	5	6
Thermal storage with condensing engines	1	13	0
Do. Do., non-condensing engines	2	5	0
Epstein storage cells	8	0	0
Storage cells at Frankfort	23	0	0
Storage cells Mr. Kapp gives as £30 to £37			

Next with respect to loss in storage—

Gas	0
Storage cells—average	20 per cent.
Transformers, high tension	25 „
Storage battery, transformers	25 „
Thermal storage—not ascertained, but considering loss by radiation, say	20 „

Loss in transmission—

Gas	1
Electricity	10 to 30 per cent.
High pressure—hydraulic	20 „
Low pressure, as at Edinburgh	50 „

It may seem strange to some minds—especially those with municipal interests—if I make the following statement : I think it is a pity that the electric light was not handed over to those who were already the purveyors of light to the public, I mean the gas manufacturers. In some cases this system has been recommended ; but even where gas companies work independently of the Corporations, I believe that they could supply the light on better terms than any separate organisation. The reasons why I believe this result could be obtained are : (1) There would be no necessity for a second staff of directors, secretaries, engineers, accountants, collectors, &c. (2) In most cases there would be no need to purchase or rent any additional land. (3) A considerable portion of the existing staff of the gas-works could manage engines (and even boilers, if such were required) with little additional cost. (4) The storage can be provided at a very low cost, and so eliminate the great difficulty arising from the great fluctuation of demand beween 1 unit and 80 units. (5) If generating stations are placed at a distance from the works, the feeding gas-mains cost very little ; the power employed for transmission is infinitesimally small ; and the loss by leakage practically nothing. (6) The cost of production per unit is very much lower than by any other system. I believe that in most cases gas of low illuminating, but good heating power, can be produced on the works for 1s. 6d. per 1,000 cubic feet and leave a profit ; no outlay having to be incurred for mains, services, and meters—mains being charged as conductors.

As an example of what may be done with even a small plant worked with three 16 H.P. nominal gas engines, and using 70 "E.P.S." cells of the "K" type, I quote from actual working returns—

The average of the results for August and October gives the cost of—

Town gas at 3s. 3d. per 1,000 feet as	1·550d.	per unit.
Labour	0·425	„
Oil and waste	0·014	„
Water	0·033	„
Total	2·022d.	per unit.

If, however, heating gas can be made at a profit for 1s. 6d. per 1,000 feet, the first item (cost of gas) would be reduced to 0·71d.; and the whole cost would be only 1·182d., or considerably under 1¼d. per unit, a cost less than is incurred in many cases where water power is employed.

I may add a few examples from Ireland. Electric lighting was started in Waterford some years ago, and the price charged for each arc lamp was £26 per annum (subsequently reduced, I believe, to £23), although the printed statements of the contractors would seem to show that the lights cost £32 each. The consequence was that the snake had bitten the infant, who died a short time since from the effects of slow poisoning ; and electric lighting has ceased in Waterford, although the steam-engines were described as "beautiful compounds." In our own immediate neighbourhood, at Larne, a town of 4,200 inhabitants, works were established by Messrs. Gordon and Co.—a firm which had immediately before declared a dividend of 30 per cent. A short time since, the able head of the firm, Mr. J. H. Gordon—a man of great and very varied attainments—lost his life by a melancholy accident. This, I suppose, disorganised the Company's business, for the plant, which was said to have cost them £8,000, was offered to the Town Commissioners for £6,000 ; but the offer was declined—one of that body stating that, at the best, six years would elapse before the concern could pay the working expenses. In Carlow, a town with a steadily-declining population of only 9,000 inhabitants, works have been established. The current is generated by water power four miles distant from the town ; but, as far as I can learn, the income of the Company could scarcely pay the rent, the upkeep of the plant, and any fair salaries to the officials English people can hardly understand how small is the number of inhabitants in an Irish country town who can afford to pay for any luxury, or incur any expenditure save what is strictly necessary. If the city of Waterford—an important port, where several lines of railway converge—with a population three times as large as that of Carlow, could not support a central station, I do not see how the latter can be successful. But Killarney, with a population of 5,500, is boldly venturing upon a similar experiment, although the town is a "Sleepy Hollow" amidst beautiful scenery except for a few months in the summer and autumn, when artificial light is not much required.

I had intended to make some observations on the testing of illuminating power, founded on the idea that the producers should get some credit when they give more than the parliamentary standard ; and, in fact, be credited with the average within certain limits. The Board of Trade has recognised this reasonable system in the case of gas meters—allowing a variation of 5 per cent., and something similar in the case of electrical tension, although a difference of 1 volt may make a difference of 5 or 6 per cent. in the light. But I have already occupied your time too long. I cannot, however, leave the main subject of this address without expressing my obligations to Mr. Thomas Patrick Travers, Assoc. Inst. C.E., and a member of the Institution of Electrical Engineers, a young engineer of great promise, who has practically studied electricity as well as gas supply. He has pointed out to me many of the facts which I have detailed to you, and has checked my statements. I think it would be well if many of our members would imitate his example, and give attention to the new lighting agent, as I have shown it is so closely connected with our future interests.

It is now more than ten years since, at the Gas and Electrical Exhibition at the Crystal Palace, you wanted me to express my views. I pointed out that in 1810, as now, the best mode of distribution was by copper wire, and the best wick for the electric lamp was carbon. Sir Humphry Davy had established these facts. But in the generation of electricity from mechanical force, an enormous advance has been made since the time when, over 80 years ago, this "new planet" first "swam into the ken" of the great philosopher ; and what is most remarkable is the fact that this marvellous growth was derived from two small laboratory experiments. First of all Oersted, in 1819, discovered that a magnetic needle suspended on a pointed pivot was deflected if an electric current was passed through a wire in its vicinity, and parallel to it ; and thus electricity produced mechanical movement. It seems strange that no one thought of trying the converse—namely, whether moving the magnet mechanically would produce a current in the wire—until 1831, when Faraday made his great discovery that, in a conductor moved into or out of a magnetic field, a momentary current was produced as it crossed what he called the "lines of force." Everything that has been done since then by Siemens, Gramme, Wilde, Wheatstone, Sadd, and others, is but the natural growth of the seed that germinated in the fertile soil of Oersted's and Faraday's intelligence. And what a growth it has been ! The telegraph, the electric light and traction, and the transference of power for over 100 miles, conversations carried on between two people separated by 1,000 miles, electro-metallurgy, the separation of rare metals from their matrices, and the thousand offices performed by this deft and willing servant of man. When your practical man scoffs at what he calls the toys of science, let him reflect on the momentous issues of these two simple experiments. In the whole history of practical science nothing is so amazing as the development of dynamo-electric energy. Compare it with the steam-engine. Now, nearly a century and a quarter after Watt's great discovery, engineers can convert into power only 10 per cent. of the heat

Digitized by Google

evolved in the boiler furnace; and, in not much more than a decade after the invention of the dynamo, over 90 per cent. of mechanical power had been converted into electricity—a sudden bound from tentative and moderate success to practical perfection. Brilliant as is the fame that irradiates the memory of Watt and his disciples, a far brighter mead of praise is due to Faraday's successors, who in so short a time eclipsed the glories of a century. And this important deduction is to be made, that it is "beyond the wit of man to devise" any system by which a larger yield of electricity can be gathered from a given quantity of mechanical force. The Goddess sprung full-armed from the brain of the philosopher.

And when we remember the small grain that was sown, and the mighty tree under whose branches we gather and find shelter, let us venerate the memory of those who devoted their lives to science, and remember that the observation of minute phenomena may, as the weather-marks in the tree guide the Indian warrior, lead us into new paths of progress, open out new vistas of thought, carry us into new fields of industry, and, by raising our thoughts from small effects, lead them to contemplate the great causes that surround us and govern our lives. Every new observation enables us to learn something more of these laws of Nature which, if misapprehended, lead to failure on failure, but which, if rightly understood, may minister to the physical well-being of man, and elevate his mind to those loftier planes of thought where he will stand but little below the highest intelligence. As he rises from level to level, his horizon widens, and each generation gathers a broader view of the vast expanse which Nature spreads before it with all the variety and beauty of a garden and the grandeur of a woodland, interspersed with the sheen of many a sunlit lake, and the sober shadows of alleys sheltered beneath the lush verdure of overhanging arches of the primeval forest.

PARLIAMENTARY INTELLIGENCE.

THE ELECTRIC POWERS PROTECTION CLAUSES.

The Joint Committee of both Houses of Parliament, appointed to consider the questions of protective clauses to be inserted in private Bills relating to electric traction Bills, met for the first time at Westminster on Monday (Lord Cross presiding). The other members of the Committee are Lord Clifford of Chudleigh, Earl Russell, Lord Rosse, Lord Ker (Marquis of Lothian), Mr. Brunner, Mr. Forwood, Major Darwin, Mr. Molloy, and Sir Bernhard Samuelson.

The Counsel appearing were: Mr. Pember, Q.C., Mr. Fletcher Moulton, Q.C., and Mr. R. Wallace, for the National Telephone Company; Mr. Pope, Q.C., for the gas and water companies, and, with Mr. Fletcher Moulton, Q.C., and Mr. E. Moon, for the railway companies; Mr. Cripps, Q.C., and Mr. J. C. Graham, Q.C., for the electric tramway companies and the electric underground railway companies; Mr. Balfour Browne, Q.C., and Mr. Worsley Taylor, Q.C., for the municipal corporations (England and Scotland); Mr. Hans Hamilton, for the Tramway Institute of Great Britain and Ireland; and Mr. R. Hunter, for Her Majesty's Postmaster-General. On behalf of the electric lighting companies and the London County Council there were no appearances.

The solicitor in the interests of electric traction is Mr. Sydney Morse; Messrs. Waterhouse, Winterbotham, and Harrison are solicitors for the National Telephone Company: and Messrs. Bedford, Monier, Williams, and Robinson are the solicitors for the interests of the gas and water companies.

We understand that there is no proposed clause before the Committee, as has been stated in the daily press.

The following is the motion on which the Committee has been appointed:—

"*Electric Powers* (*Protection Clauses*).—That a Joint Committee of Lords and Commons be appointed to consider and report whether the grant of statutory powers to use electricity ought to be qualified by any prohibition or restriction as to earth return-circuits, or by any provisions as to leakage, induction, or similar matters; and, if so, in what cases and under what conditions. And if the Joint Committee are of opinion that any such prohibition, restriction, or provision should be enforced, to settle the necessary clauses. That a message be sent to the Lords to communicate this resolution, and desire their concurrence."

MONDAY, JUNE 19TH.

Sir COURTENAY BOYLE, K.C.B., was the first witness called. In reply to the Chairman, he said that as permanent secretary to the Board of Trade he had had all the questions about the telephones and the circuits submitted to him. The telephone and telegraph companies (in which he included the railway companies using the telegraphs) had sought for protective clauses in the Electric Lighting Provisional Orders, in Tramway Provisional Orders, and in Tramway Bills; that was to say, the telephone companies had sought to avoid interference with their circuits by tramway companies using electricity for traction purposes, and by electric lighting companies when they used high currents on their circuits. The telephone and telegraph companies, speaking generally, used the earth for the return, but not invariably so. But some sections of the telephone system, and, generally speaking, the General Post Office telephone system used the metallic return. The earth system was, however, very largely used by the telephone companies. The action of Parliament had not been uniform. There were four clauses which had been from time to time adopted by Parliament; one called the "Plymouth clause," which was inserted in six Bills in 1889. The effect of those clauses was to give varied degrees of protection to the telephone companies. In some of the clauses the protection was to be given in respect of lines existing and afterwards to exist. The degree of protection given by the four clauses varied very considerably.

The CHAIRMAN: Is it, in your opinion, desirable that this question should be settled in order to have a model clause?—Yes; the Board of Trade found, as regarded Provisional Orders, the telephone companies were again pressing, and reasonably so, for protection to be given to them. There was a variety of practice by Parliament, and by the Board of Trade, with regard to Provisional Orders. After a meeting held at the Board of Trade a representation was made to the Chairman of both Houses by the Board of Trade, suggesting that it was desirable that Parliament should lay down a principle governing the amount of protection, if any, which the telephone and telegraph companies were entitled to receive in this matter. Sir Courtenay Boyle then explained the meaning of the word "ohm" as the unit of resistance, and the other units, the volt and ampere. The telephone companies used the earth for their return circuit generally speaking. The telephone and telegraph companies used very small currents at very low pressure. The telephone, not for the purpose of ringing a bell—that was done by telegraph—but for the purposes of the current used in conversation, was a very small current indeed, something like a millionth part of an ampere. Speaking generally, the telegraph companies used currents from one hundredth part to a quarter of an ampere at a pressure of from 10 to 50 volts. The electric lighting companies used a current of something like 100 to 5,000 amperes at a pressure of 100 to 10,000 volts. Therefore, the Committee would see, as regarded the electric lighting companies, and, similarly, as regarded tramway companies, although theirs was not so high, the current used was very high as compared with the current of the telephone companies. Therefore, the phrase had been used over and over again that this was a matter of electrical disturbance, and the electric lighting companies and the tramway companies were the wolf, and the telegraph and telephone companies were the lamb in this matter. There was no doubt that either by leakage or by induction, the tramways, when they used electricity, might inadvertently cause electrical disturbance in the vicinity of their circuits. That disturbance caused material interference with the very delicate, sensitive instruments used by the telephone companies and the telegraph companies. The metallic return circuit was used in some systems. The telephone companies have got the earth, and used the earth, and they pleaded to be allowed to use the earth by prescriptive, as well as by inherent, right. Electric traction, both on tramways and railways, was growing in popularity, and would grow still more if the question of the use of the earth return could be settled.

Have there been any decisions on the question?—Yes, the case known as the Leeds case, which was between the National Telephone Company and the Leeds Corporation. A special inquiry was organised by Mr. Macrory, whose report showed that undoubtedly there was interference with the sensitive instruments of the National Telephone Company. In delivering that judgment, Mr. Justice Kekewich said, "True it is that the analogy introduced above," that is, the use of land for extraordinary purposes, "holds to this extent: the plaintiffs are using the land for extraordinary purposes"—the plaintiffs being the Telephone Company—"but admittedly it is a lawful purpose, and though under an obligation to obviate mischief from their own operations to their neighbours, they are under none, in my judgment, to protect themselves from the defendants or others." The learned judge went on to say that the defendants' plea was good in law, and they are not responsible to the plaintiffs for any mischief caused by their working. The defendants' authority was derived under a Provisional Order confirmed by Act of Parliament. A little further on the Judge said: "The defendants are expressly authorised to use electrical power, and the Legislature must be taken to have contemplated it and to have condoned by anticipation any mischief arising from the reasonable exercise of the power." Practically, the defendants, that is to say, the Tramway Company, enjoyed certain advantages from the decision, because they had a Provisional Order confirmed by Parliament.

Mr. FORWOOD: Assuming that there is no electrical disturbance such as you have described in a district used by the telephone, would the use of the earth as a return circuit give us as good a result in point of hearing as would a metallic circuit?—That is a scientific question which I can only answer to a certain extent. When the earth is used as a return circuit for telephoning, it must follow that there is a certain amount of electrical disturbance. I think I should have the support of the telephone companies' experts, when I say that perfect telephoning is done by metallic circuiting and not by earthing at all.

Mr. BRUNNER: Are there no more cases of mischief resulting from electrical disturbance than those you have mentioned?—The number of tramway companies using electricity at present is very small, and the electric lighting companies are forbidden to use earth, so that the danger does not, and cannot, occur very often; but if you sanction electricity for traction purposes, the number of instances in which there might be danger would grow.

Earl RUSSELL: The argument is that the expense is much less to the telephone companies to use the insulated returns than to the tramway companies?—That is the argument advanced by the tramway companies, and there is a great deal of weight in that. The tramway companies say it will cost us a very great deal to protect our system absolutely from danger. It would not cost the telephone companies very much, and on the other hand, the telephone companies say, "We have established a very large and far-reaching system of telephoning, which is very largely in the interests of the public, and we do not see why we should be obliged to alter our system because other people may injure us."

Digitized by Google

Lord CLIFFORD: With regard to tramways, do any tramways use earth returns?—Not intentionally. I think I am right in saying that there is no railway company or tramway company which deliberately uses an earth return. Earthing occurs by accident and by mishap, but not by intention.

Sir BERNHARD SAMUELSON: Do the electrical tramway companies admit responsibility regarding accidents occurring through leakage or earthing?—They say it is almost impossible; the phrase used is "absolutely impossible." There is an instance brought forward from Buda Pesth, where it is stated that it has been done.

The CHAIRMAN: You are representing neither one interest nor the other; you have simply come to put before us the matter as it was placed before the Board of Trade?—I have no interest whatever to represent. The difficulty has been so overwhelming that the Board of Trade itself has decided as regards its own Provisional Orders that we had better appeal to a stronger tribunal to settle what we had better do.

Mr. PEMBER said they proposed to call a witness who had examined the tramways at Buda Pesth.

The CHAIRMAN: I understand the Post Office wish to be represented here.

Mr. HUNTER said the Post Office at present was rather in the position of watching the Committee. The Post Office had no grievance against the tramways companies or the railway companies at present, because they were protected by what they thought were sufficient clauses. But his Lordship would understand that the Government must reserve to itself the right at any time to seek such protection from the hands of Parliament as they thought necessary. Of course, he was speaking with all respect.

The CHAIRMAN said that if Mr. Preece wished to say anything, the Committee would hear him.

Mr. PREECE was then called. In reply to the Chairman, he said that he was engineer-in-chief and electrician to the Post Office, and President of the Institution of Electrical Engineers. He had given a great deal of attention during the past ten years to the disturbance created in the existing wires by the new and important applications of electricity to electric lighting, and to the working of railways introduced during that period. They had found their telegraphs and telephones were gradually being disturbed. The disturbance arose from two causes: The first was due to the passage of currents of electricity through the crust of the earth; and the second arose from what was called induction. The currents through the earth were the more serious ones. The effects due to induction were easily removable, but, of course, it would cost money. The earth had, from the earliest days—from 1837—been used for the return half of the circuit in telegraphs. A wire, say, extended from London to Glasgow. In London it was usually attached to the great water and gas-pipe system of London, and there it made contact with the earth; in Glasgow the same. When they dealt with the great mass of the earth between London and Glasgow, that resistance was practically nothing. The result was that, electrically, they only had to deal with the resistance of the overhead or underground wire between London and Glasgow. The whole telegraphs of the world at the present moment were worked with the use of the earth, and the telephone, being the child of the telegraph, had originally, in America, also used the earth as part of the circuit. The first telephone which was fixed in London was fixed on a metallic circuit. Ever since then the Post Office had invariably used metallic circuits. The Telephone Company, on the other hand, in their town systems used the earth, but in their trunk systems, which were very extensive, used metallic circuits. On railways, where telegraphs were used for the regulation of traffic, and where electric block signals were used, the earth was used; so that at the present moment the earth was used universally for telegraphs on railways and for Post Office Companies, almost universally for block signals, and very generally indeed for telephones. With the electric light the earth was forbidden, except as provided by Clause 9 of the model Provisional Order. Under Clause 9 the use of the earth was allowed by the Board of Trade, and had been approved of by the Postmaster-General in the case of the London Electric Supply Company. He had prepared a diagram showing how a district became permeated with earth currents. The City and South London Electric Railway started working in 1890. It did not designedly use the earth The return circuit was made by means of the rails, and also the two tubes of the railway took up some of the return currents, acting as the earth. There were two metals to carry the train, and there was a third metal in the centre which enabled the locomotive to pick up the current. The current when picked up passed through the electro-motor on the locomotive, and went through the wheels to the metals, and, theoretically, it ought to go entirely through the metals back to the central station; but, as a matter of fact, it did not. The metals were uninsulated, and the electricity leaked. He exhibited an imaginary diagram, to illustrate what took place when a train was about to start at the Monument at one extreme end, and also what took place when there were two other trains on the line. The curves showed the direction of the earth currents. These earth currents extended to such a distance that they had disturbed the observing instruments at Greenwich, and they were observed also as far away as North Walsham, in Norfolk. The currents passed through a wire extending from London to Norfolk, and they were there recorded on instruments. In order to identify these currents, and to be quite sure that they were due to the working of the train, they took a part of the Norfolk circuit—that was to say, between the General Post Office and Tottenham—and watched for those varying fluctuating currents, and he had marked the currents on his diagram as they rose up and down, and followed exactly the movements of the trains. At Greenwich, when the train service ceased at night the disturbances ceased at the same time. The observations at Greenwich and those at the Post Office always tallied exactly with the working of the traffic. After reference to the effect of leakage currents observed in the south of London, Mr. Preece said that he was rather anxious to impress on the Committee the importance of this question of electric pressure found between gas and water pipes, for it was by far the most serious disturbance that was likely to be brought about. The effect of it would be, if not checked, that the water pipe, or the gas pipe, whichever was connected with the positive side of the current, would, in course of time, be decomposed away. The constant action of the current meant electrolytic decomposition, and unless some steps were taken to prevent this there would certainly be leakage of gas, or leakage of water, and accidents would follow. Sir Courtenay Boyle mentioned the fact that such decomposition occurred in Preston. Major Cardew had personally examined these things, and perhaps he might be called before the Committee to give personal evidence. There was also a great source of danger to the block system of the railway companies. In the year 1880, he thought the London and North-Western Railway Company lighted up the harbour at Holyhead with the electric light. They had five arc lights, with five dynamos. The first effect was to break down their block signals. Their block signals got very much disturbed within a mile of the station, but that was completely cured by making the block signals with a metallic circuit. The Post Office maintained nearly all the block signals in Ireland, so that as a maintainer of block signals his experience was quite as great as that of most of the railway companies in the country. The moment a train stopped, the earth current suddenly rose, as there was a great rush of electricity to stop the train. At that moment a powerful current is sent through the whole region of the earth around the tramway, and the block signal in the case of a railway company is lowered to "all clear," and obviously that might lead to very serious danger. That might be averted by a metallic circuit on the block signals affected. As a rule, the disturbance only extended about half-a-mile to a mile—the average would be about half-a-mile, and it would only be necessary to put up a second wire for those block signals which were likely to be disturbed. He had had the Liverpool overhead railway as carefully examined as the South London Railway, and the curves there were exactly similar. In the case of Liverpool, however, the metals were planted on continuous wooden sleepers, and they did not make very much earth, the result being that the currents were very much less in intensity; there was partial insulation, in fact. In the case of the South London Railway he had not yet heard of any absolute disturbance to any block signal, or even to a telephone. He had taken the South London Railway as an indication of what they were likely to see. If all London were percolated with electric railways, as they hoped it would be, then the injury was almost certain to be serious. He should like to mention that at Blackpool the same current which lowered the railway signal also fired the time current. There, at one o'clock, the Post Office transmitted a current from Greenwich to Blackpool, and this time current had been fired a minute or so before its time by these currents from the electric tramway. In his view, the use of the earth by railways and tramways should be subjected to the supervision or the approval of the Board of Trade and the concurrence of the Postmaster-General, as in the case of the electric lighting companies. He did not go so far as to say that the accidental use of the earth should be prohibited—it could be used under proper supervision. There was on difficulty whatever in virtually insulating the metals in the South London tubes. He thought the current from that railway had increased owing to imperfection in the joints of the tubes.

By Mr. MOLLOY: The disturbance at Holyhead was avoided entirely by metallic insulation. In that particular instance they would have done better if they had made a return for their electric light circuit. In the case of the South London Railway this indiscriminate and accidental use of the earth must mean a very considerable waste of energy, and the working expenses at their central station must be increased considerably by this energy which is wasted in the earth.

By Earl RUSSELL: It was true that the energy required to ring the division bell did not amount to the thousandth of a horse-power; but it must be remembered that that was picking up the energy in a house which was an infinitesimal fraction of the area disturbed by this railway. The disturbance recorded in Norfolk was observed on a wire from the General Post Office. It was not disturbed along the earth all that way; it merely recorded the fact of the disturbance at Stockwell.

By Mr. FORWOOD: As regarded the Post Office telephones, they always used metallic currents, and he did not think a telephone circuit was complete or perfect without a metallic circuit. But the earth was absolutely essential for the working of the telegraphs. They could scarcely work their complicated multiplex and quadruplex system of telegraphs if they used return wires. If they used return wires the whole efficiency of the service would be reduced one-half, the cost of maintenance would be doubled, and the cost of working would be doubled, therefore, financially, it was impossible to use return wires.

In reply to the CHAIRMAN, at the request of Mr. Pember, the Witness promised to inform the Committee subsequently how many miles of telephone the Post Office possessed. They had about 7,000 telephones, and they were now erecting about 4,000 or 5,000 miles, so that he would be within the mark when he said that they had perhaps 20,000 miles.

The CHAIRMAN: Could you repeat those experiments at Greenwich, and let us have the result of them again?—Yes.

Lord ROSS then took the chair, Lord Cross being called away by other Parliamentary business.

Mr. POPE asked if the witness might be allowed to explain what he meant by accidentally using the earth.

Mr. PREECE said that no tramway company, as far as he knew, designed their electrical system so as to use the earth intentionally as the return, but it happened that when it rained, and when the bare copper wire was in connection with the ground then the earth came in accidentally to assist the transfer of the current and then the disturbance was observed.

By Mr. FORWARD: Alternating currents would not affect the gas and water pipes, but continuous currents would. In the case of continuous currents the disturbing effect could be very much diminished by replacing the whole of the gas system, and the whole of the water system in

Digitized by Google

direct communication with the return system of the railway, so that with proper supervision the disturbance might be relieved.

By Sir BERNHARD SAMUELSON: He should qualify what he had said about all the telephone circuits of the Post Office being metallic. They had in some outlying districts of Ireland and Scotland, single wires for short distances. In those cases, they did not come near any telegraph; there was no electric light and no disturbing influences anywhere near; therefore, they did not put a second wire; but in all large towns, on all telegraph poles where there were other circuits, and in all cases where a second telephone circuit ran they invariably made a metallic circuit. Why the telephone people had not done so in all cases they must answer for themselves.

The Committee then adjourned.

TUESDAY, JUNE 20TH.

Mr. WM. E. L. GAINE (General Manager of the National Telephone Company) was the first witness. In reply to Mr. PEMBER, Q.C., he stated that the licence from the Post Office, under which the Company worked, dated from November 29, 1884, and was for 31 years, so that it would expire in December, 1912. It extended through the whole of the United Kingdom. The estimated annual number of calls was 109,339,220; the estimated number of messages 218,673,440; the annual value of exchange revenue and fees at April 30th was £554,171; the average cost per message was 0·608 of a penny; the total number of exchanges on April 30th, 506; the number of exchange and private lines, 60,155; and the total mileage of wires at the same date, 90,746. The estimated yearly number of messages between Manchester and Liverpool was 295,200, at an average cost of 3d. per message; Newcastle and Sunderland, 233,472, at 1·27d.; Leeds and Bradford, 189,696, at 1·14d.; Edinburgh and Glasgow, 108,552, at 2·65d.; London and Liverpool, 48,024, at 1s. 5·57d. The whole of the exchanges, with one or two exceptions, had been built up on the earth-circuit system, which was adopted in nearly every country—the United States, France, Germany, and others. The largest telephone system in any one town was that of Berlin, with 17,000 subscribers, which was entirely on the earth-circuit system. It was in the hands of the German Government. The earth circuit was amply sufficient for all commercial purposes where they had a local exchange to deal with, *i.e.*, where they could concentrate all their subscribers into one central exchange; if subscribers desired to use the long trunk wires, then they must have something suitable for that particular service. He did not suggest that the earth-circuit principle would meet the case of the subscriber who desired to have daily communication between London and Liverpool. The plan of the National Telephone Company was to adopt that system which was most suitable for the service required. If a man in Liverpool desired to have communication with a man in London he was put on to a metallic circuit at the Liverpool end, had the best instruments for long-distance speaking, and was charged a reasonable price. If a man desired to talk only with his neighbours and correspondents in Liverpool, then he did not require the same expensive service, and the earth circuit gave, as a matter of fact, an efficient and a good service.

The CHAIRMAN: Does that apply to Manchester?—Manchester and Liverpool, but I should not like to carry it much farther than that. There were conditions under which metallic circuits were essential, and metallic circuits were, at any rate, a considerable aid to giving an efficient service. In the case of London it had been somewhat notorious that as the system had rapidly developed on an earth-circuit principle, it did not give a service which the public were entitled to look for, and the National Telephone Company had had to look about them, and they had spent huge sums of money in the past few years in order to put first of all the junction wires between their London exchanges upon metallic circuits. They were now carrying that to its logical conclusion, and putting the whole of the subscribers in London on a metallic circuit. They had an area in what was known as London of 5,000 square miles, containing no less than 23 exchanges. Where they could concentrate their subscribers into one exchange, then, for local purposes, the single wire was sufficient; but with an area like London, where subscribers had constantly to pass through two and three exchanges to communicate with one another, then a metallic circuit was an aid to efficient service. In Liverpool they had between 3,000 and 4,000 subscribers concentrated in the central Liverpool exchange, and he did not hesitate to say they were giving them a thoroughly efficient and thoroughly good service.

Mr. PEMBER: At a low rate?—Yes, they had a large number of subscribers in Liverpool who paid an enhanced price because they wanted something better than the local service. They had about 3,500 wires, all concentrating overhead into the Liverpool central exchange.

Supposing that electric traction of a similar character to that which is employed on the tramway at Leeds were sanctioned and used on the Liverpool tramways, would all these lines of wires be so disturbed that you would have to turn them into metallic circuits?—Judging from the experience the Company had at Leeds, undoubtedly that would be so; those lines would be valueless for commercial purposes. I am particularly anxious to impress my views with regard to this on the Committee; Mr. Preece, in his evidence yesterday, was very strong as it appeared to me that the remedy of the Telephone Company was to duplicate their wires, but I doubt whether Mr. Preece, or anybody else, realised what that meant. This system has been built up for a number of years, and their 3,500 or 4,000 wires coming into the Liverpool Exchange had to come in all over the roofs, for which switchboards, &c., have been put up. The great bulk of the switchboards of the country were single boards; it meant the taking out of those, an enormous work, and the re-erecting of the entire system, and he had no hesitation in saying that if the Leeds tramway were planted in the City of Liverpool to-morrow Liverpool would be deprived of the telephone for at least five or six years. He would not undertake to re-duplicate the wires and re-arrange that system under that time.

You have said nothing of the enormous cost; those switch-boards are very expensive, are they not?—A switch-board for an exchange the size of the Liverpool exchange would not be less than £20,000. That, of course, did not take into account the cost of wayleaves, and ordinary repairs and maintenance. The National Telephone Company had periodical returns taken of calls upon the principal exchanges, and the number of calls in one day on the Central Exchange in Liverpool was no less than upwards of 44,000. Calculating a call between one subscriber and another as equal to two telegrams, they had thus 88,000 telegrams in one day, and it might be easily seen how great the deprivation of this means of communication would be to the commercial community of Liverpool, and, undoubtedly, they would be deprived of it, and for a long period. The Leeds tramway ran through one of the outskirts of Leeds, and it disturbed, comparatively speaking, only a few lines—26 lines. They brought an action against the lessees of the tramway to see if they had a right to some legal protection at common law; the decision of the Court being against them they had to find their own remedy. Although they had only 26 lines disturbed in Leeds, the cost of putting them on to a small extra exchange was between £600 and £700. If this were carried out to its logical conclusion, and assuming that the traction were to be universal all over the country, he estimated that it would cost the Company not very far from two millions of money.

In answer to Mr. CRIPPS, Q.C., who cross-examined on behalf of the electric traction interest, witness said Newcastle and Hull were examples of exchanges on metallic circuits. In those cases they charged a rent of £10 per annum to subscribers. In Liverpool also the rent was £10.

When you were working London on the earth system, what was the rental?—£17 upon a five years' contract, and £20 on one year's contract.

Then you have not charged more where you have the metallic circuit return than where you have an earth circuit return?—That is so.

Suppose in any district you had electric traction without perfect insulation, would not you say that a metallic circuit would be the best, and perhaps the only complete protection of the telephone?—I should say complete protection would be afforded by perfect insulation of the traction. He had no hesitation in saying that if all their system were put on to metallic circuits, and there were no question of time, convenience, or cost, and that the reasonable precautions were taken by the tramway traction, probably there would be no disturbance. Asked if he thought there was any practicable method by which electric traction and telephones might be used in reasonable contiguity except by putting the telephones on the metallic circuits, witness said he should prefer that an electrician should answer that. In London the alterations had extended for practical purposes to the whole of the junction wire on the different exchanges, and some proportion of subscribers' wires had been replaced by cables, but a very considerable cost had yet to be met in the alteration of the switch-boards. He could not give the cost up to the present time in really reliable figures, but he should think it was about £100,000.

Was the alteration made in London in order to improve your system because the earth system is not sufficiently efficient?—Probably, under the conditions existing in London, yes.

You said the earth system was in use on the Continent and in America. Take Paris, for instance?—I said generally; in Paris it is an entirely underground system. The charges on the metallic circuit in Paris, to the best of his belief, were £16 a-year rental, in addition to which subscribers had to find their own instruments.

And how does that compare with the £20 paid in London for the earth system?—The £16, plus the cost of the instruments, which makes it £17 (say), should be compared with the £17 a-year for a five years' contract in London. The French Government, however, had nothing in the way of wayleave to pay, whereas in London they had to pay many thousands a year. Overhead wires were very much cheaper initially, but very much more costly in their maintenance. They had about the same number of subscribers in Paris as they had in London; a trifle more, perhaps.

But there is a smaller population there?—Yes.

So that you give a better system on the same or better terms to a larger number of subscribers, in proportion to the population, in Paris than in London. Does not that suggest to you that by giving the better article—a metallic system—you get a larger number of subscribers, and can work the system cheaper?—No, I do not think so. The answer to that is, compare Paris with Berlin, where you have nearly double the number on a single-wire system. There was no doubt that as the service had grown up in London the earth system had not given so much satisfaction as the subscribers were entitled to; but London, telephonically, was an entirely different problem to any other place in the world; there was no place where there was so enormous an area and so great a population, which, of course, necessitated a great number of exchanges.

Surely the extent and population ought to make London the cheapest place in the world?—It is not concentrated telephonically.

Up to the present time you have had a large number of these special clauses; are you aware that wherever you have these clauses it is impossible to have electric traction?—I am not aware of that; on the contrary, I should like to say that in South Staffordshire a tramway company is running to-day, and is running subject to those clauses.

Can you give any other instance?—I am not aware of any.

You stated, I think rather widely, that in the United States, on the Continent, and everywhere else, the general system was the earth-return system; is not the metallic-circuit system very largely used in America?—For all very long distances it is the same as it is in this country. In America they have a principle of working what they call first, second, and third class; if a man desires to have long-distance telephony, or even telephony for a moderate distance, he goes on to first class, and has metallic circuits and the best instruments, for which the charge in New York, I believe, is £40 per annum.

In answer to Mr. BALFOUR BROWNE, Q.C., witness said he had no idea what the mileage of tramways in this country was. He admitted that

Digitized by Google

every tramway must be laid down either under an Act of Parliament or a Provisional Order, whereas the tenure of their telephone lines was only by license of the proprietors of the houses over which the lines were laid, and, unfortunately, was generally limited to three months. He believed tramways were being worked by electricity in Walsall. Asked if this did not harm their telephones, witness said there had been some complaints. He had heard they were working there under a protective clause.

Are you aware that the Corporation of Walsall said they would rather give up the telephone than the electric traction?—No, I am not; so far as I know no application has been made to the Corporation. Asked the same question with regard to Blackpool, he thought very likely it might be so in that case, because, to a sea-side town like that an electric tramway along the sea shore was an attraction, and there was also a comparatively limited number of subscribers. In further cross-examination, witness submitted to the Committee that the National Telephone Company were really performing, under license from the Postmaster-General, a part of the service of the State, and paid the State on their present annual revenue something like £55.000 per annum. There was no provision in their licence as to the charges which they were to make to the public, similar to the clauses in the Tramway Acts, simply because they had no corresponding powers to run their wires. He was aware that the Postmaster-General had given public notice that no further licence would be granted to any telephone company without the use of a metallic circuit.

Continuing, the WITNESS said that the New Telephone Company started with the intention of always having metallic returns, and charged at first £12. 12s., as against the present charge by the National Company of £20. The total mileage of the Companies' wire was 90.000 miles. The New Telephone Company did not start as the Mutual at Manchester, but the Mutual started as a separate undertaking, and the New Telephone Company subsequently acquired it. The price charged by the Mutual was lower than that of the National. The capital of the National Company was £4.000,000, but he could not say how much of that had been expended.

Mr. BALFOUR BROWNE: The New Telephone Company was not amalgamated with you, I believe, but all their shares were bought up by you at a premium?—Not all the shares.

Most of them?—A large proportion. They were bought at £5 a share, on which £4 was paid.

Is there a single company which has been started with a licence that your Company has not bought up?—I explained to the Committee that the whole of the licences were practically held by our Company, and that the whole service was done by the National Telephone Company. I think we have bought up 13 different licences. He could not say what was the length of the Company's wires in the administrative county of London, but it was more than 6,000 miles. He could not tell the amount of capital which had been expended upon them. His estimate for making a complete change from earth returns into metallic returns in London would be about a quarter of a million sterling.

By Mr PEMBER: He could not say whether the Parisian telephone system, which belonged to the Government, was worked at a profit or loss. There would be nothing in the accounts of the Government equivalent to the royalty which the National Company paid to the English Government, which amounted to £55,000 per annum, being 10 per cent. on the gross receipts from the exchange business. On the net receipts, of course, it would work out at much more. He was not very conversant with the Vienna telephones; there was a company, he knew, but he thought the State had acquired most of the services. He did not know if the system was as good as at Paris. At Berlin the telephones belonged to the Government, and were worked entirely on the single-wire system with an earth return. The number of subscribers at Berlin was larger in proportion than in Paris, and larger, he thought, than in any other town in the world. The South Staffordshire Company, the City and South London, and the Liverpool Overhead Railway, were instances of companies which worked under the Plymouth Clause, and the Blackpool Corporation had just elected to put the same clause into their Order this year. In the action against the Leeds Tramway Company, a list of the towns in which the Post Office competed with the Company was put in which showed that they had 1,325 subscribers in the country. He was not very well able to say whether the Post Office business was a growing one or the reverse.

By the CHAIRMAN: A large amount had been spent by the Company during the last two years in altering the service, and though there had been consequently some disturbance of the system there had been no electrical disturbance. The great difficulty was that when they sent a man on to the roofs to attend to the wires the wires came in contact, and it led to a great deal of disturbance.

The CHAIRMAN: I did not understand why you said you could not alter your system at Liverpool without stopping altogether for five or six years?—If the railway were worked it would disturb us so as to make our system unworkable. We can go on altering the system and carry on business at the same time.

By Mr. FORWOOD: If the tramways were to be worked by electricity they would want four or five years' notice of it. The underground system was more economical in maintenance, but it did not give so efficient a service telephonically as an overhead wire. There was nothing so good as an overhead wire.

In your judgment a metallic circuit is better than the earth?—For long distances, certainly not for local service. That is the whole point I endeavoured to impress upon the Committee.

Have you had any experience of subscribers in London complaining of disturbance, say, between Whitehall and the City, and have you recommended the putting up of a metallic circuit at an extra cost?—There may have been individual cases of that kind. If the Committee could see one of the switchboards they would realise the fact that they could not deal with many of such cases unless they took the whole thing out, and put them all on one system. The reason for the recommendation was that they were giving here two exchanges, and where they had that condition of affairs, he said at once that a metallic circuit was an aid to good work. There was at present a metallic circuit from the City to the House of Commons.

By Mr. MOLLOY: The cost up to the present of converting the earth system in London into the metallic system had been about £100.000, and before it was completed it would cost a quarter of a million. In London, where they had extraordinary complications to deal with, the metallic system was the best for good work; but in Liverpool, where there was concentration, it was not the best for telephony for local purposes.

By Lord CLIFFORD: In putting up a new system, the difference in cost between metallic and earth returns would be that the former would cost a third or half as much again. As to the cost of maintenance, the only estimate he had given was as between underground and overhead wires.

By Sir BERNHARD SAMUELSON: The circumstances which led to the placing of the wires underground at Newcastle were that the Corporation did not like overhead wires, and gave cheap facilities for putting them underground. The reason that they were placed underground in Hull was on account of the town being dominated by the docks, and it was thought by the engineer better to have them underground than overhead. The Company's patent was for 34 years, and expired in 1912.

Dr. JOHN HOPKINSON, F.R.S., examined by Mr. WALLACE, said that as regards the comparative cost of the earth's circuit and the metallic circuit, it was pretty obvious that for materials the cost of the metallic return would be double, but there would be some items (for example, the poles and the cost of erecting the poles) which would not be increased in that ratio. If the rights of taking up the streets were given to the Company, a great deal would be saved by putting the wires underground, especially as they would be freed from the payment of way-leaves. If the work of the electric lighting companies was properly carried out it constituted no detriment to the telephone companies as at present wired, because the electric lighting companies were bound to insulate their whole system.

Would a tramway company affect the telephone to any greater extent than an electric lighting company?—If electric lighting companies were to get their leads to earth at both ends it would be, broadly speaking, the same. There would be disturbing influences arising from contacts with the tramcar. He made an inspection of the Leeds tramway in 1891. He also went into the Leeds telephone exchange, which was on the single-wire system, and on using the telephone he heard a noise which would rise and fall at a varying pitch, so that it was impossible to converse with any distinctness. He could hear the cars stop, and could hear distinctly that there were two cars running by the difference in the pitch of the note. The sound diminished in loudness as the cars took a larger or smaller current. When the cars stopped there was practically no disturbance.

In your opinion was that noise such as would prevent the proper working of a telephone exchange on the single-wire system?—Yes, undoubtedly it was. He had had an experience of telephone exchanges worked on the single-wire system where there was no electrical tramway, and found that there was no disturbance. In London the system was now sufficiently good for all practical purposes. It had much improved in the last three or four years, and the improvement was still going on. With regard to the cost to the traction companies of making returns to the station isolated, he said there were many ways in which the tramway company could convey their currents for the purpose of driving their cars. The system of overhead conductors was most largely employed. In that case no doubt, a certain slight additional complication would be introduced in using two conductors overhead instead of one, but, on the other hand, some advantages would result from doing it. The pressure at which the cars could be driven would be double, because the danger to the public arises results from the difference of that pressure from the earth pressure. Being thus able to work at double pressure, they could work with half the current as measured in amperes. If they were allowed to use the double pressure they would diminish the capital outlay, and also diminish the running charges. He had not seen a double-trolley overhead system of tramcars; but at Vevey he had seen an arrangement with double wires, in which the overhead conductors formed a tube, and the conductor went alongside the tube. With regard to double tramways underground, he went to Buda Pesth for the express purpose of seeing how the system was carried out there, and whether it disturbed the telephones. There were 22 kilometres of single line; but as the line was almost all double, that represented about 11 kilometres of double line. The conductors throughout were laid out underground. The conductor was carried underneath the rail at the side. The railway was constructed by Messrs. Siemens and Halske. Underneath the rail was a culvert, and in that culvert were two conductors of angle iron carried upon insulators. The culvert was formed of castings, and was made up, between those castings, of concrete and brick. Both those conductors were insulated. He inquired especially of the telephone authorities in Buda Pesth whether there had been any disturbance upon their telephones from the tramways, their system of conductors being entirely by earth return. He listened on the telephones, and heard no disturbance. He could detect absolutely nothing. He travelled upon the tramways the same day, and supposed that there were between 50 and 60 cars running at the time. The insulator on each of the cast-iron formers which carried the rails, and the angle iron which conveyed the current, was attached to the insulator which was produced for the express purpose of insulating the angle iron. He had no doubt that such a system as that could be worked so as to pay the shareholders. The only disadvantage that he noticed was that the slot in the rail was about 1¼in. in width. If he were doing the work himself, he should not use so wide a slot as that, but only ¾in. wide. All that he would have to do would be to carry the little instrument which made contact with the two conductors through the slot.

Mr. MOLLOY: In this Buda Pesth tramway is there any earthing except it may be accidental leakage?—No, both sides were perfectly

Digitized by Google

insulated, and the engineer had to keep it perfectly insulated at all times.

By Mr. WALLACE: In addition to the forms of traction of which he had spoken, of course there was the system with accumulators which had been tried in America with great success from an engineering point of view undoubtedly, but had hitherto been very costly.

In reply to Mr. MOON (on behalf of the railway companies), the witness described the system of block signalling, in which he said the current used did not exceed an ampere, but probably would be less, the voltage being three or four volts, representing only a normal telegraph current; the leakage of such electricity as was used for traction would be sufficient to operate the signals. If there were favourable circumstances, such as gas or water pipes, in the direction of the signals, the effect of the leakage would be felt at a greater distance. He had seen the arrangement of signalling at Blackpool, and observed the experiment as to how far the tramway current disturbed the electric signal. He heard the bell ring twice, and the signal was pulled down from safety to danger twice, without any intentional action on the part of the signalmen.

Mr. MOON: I do not need to ask any such obvious question as to what the effect of that would be, but the signalman would have no means of knowing whether it had been operated upon by one of these vagrant earth currents, or whether it had been operated from the next box?—No; none. In his opinion the remedy for that state of things was the insulation of the return currents in the case of the electric tramways.

By Mr. WALLACE: With regard to the currents sent to earth by the telephone company and the tramway company, there was a considerable difference in the electrolytic action upon the pipes and metals in the street. The effects and currents from electric lighting on gas and water pipes was becoming a matter of common observation both in this country and America. The pipes got oxidised, and there was very serious danger arising from it. On the other hand, from the telephones it would take 50,000 years to oxidise. It was probable that signals were altered by natural electrical force like lightning. He did not know that the Caledonian Railway Company had made an absolute metallic return between their signal boxes in every case; although in electric lighting no earth current was allowed, occasionally there was unavoided leakage—he would not say unavoidable leakage. If there was a material leakage, say 1-200th or 1-300th of an ampere it ought to be cut off from the system at once. The Board of Trade put the companies under obligation to cut off any consumer whose leakage was less than 1 5,000th ohm. Induction would be much more if the lines were parallel; for induction they must have a certain amount of parallelism in the wires. The Southend system was not precisely the same as that at Leeds, as at the former place they had an insulated return by the rails. The cost of the Buda Pesth system was about £4,000 per statute mile, which, of course, included the rails.

Mr. BALFOUR BROWNE: Supposing two things to be coincident—a tramway to be made and a telephone to be laid—would not much the cheapest method be to double your wires in the twist? I should say not. It depends on the scale on which the work is carried out.

Do not you think, even without tramways, that is what the telephones are coming to?—In London special conditions apply. If they could get the right of taking up the streets and laying the conductors underground, I have no doubt they would rather face any cost there may be, rather than have the cost of maintaining overhead conductors and the cost of wayleaves.

Mr. CRIPPS: Which do you get a greater disturbance from, leakage or induction?—From induction, I should say. If electric tramways were working in a town, they could not entirely eliminate the disturbance so long as they had earth connection on any part of the telephone system there.

Mr. POPE, Q.C., here asked leave to make an application on behalf of the gas companies. Since yesterday, in consequence of an answer given by Mr. Preece as to the connection of the gas pipes and water pipes with the conductors, the gas companies had become very considerably alarmed, and more especially because they had found that, in the case of Blackpool, the use of the gas pipes as a link in the return circuit had been recommended, and actually adopted. The gas companies were not at the moment before the Committee, but they would very much desire to be, because they thought great danger was involved in the suggestion which had been made, and they would like the opportunity of giving some evidence with regard to the matter. It might be necessary that a petition should be presented to entitle them to appear. It would be a most dangerous thing if their pipes were made use of.

The CHAIRMAN: In Preston that was so.

Mr. POPE: Yes.

In answer to Mr. HANS HAMILTON, Dr. HOPKINSON said he did not advocate the use of accumulators as a commercial possibility. The question of a circuit return was largely a matter of expense, but there were other considerations. He objected to doubling the wires overhead.

Dr. EDWARD HOPKINSON, C.E., said his firm had supplied the plant for the City and South London Railway, as well as for tramways on the Continent and in the Colonies. He gave hypothetical estimates for various tramways with completely insulated returns.

Lord KELVIN, in answer to Mr. PEMBER, stated that he was intimately acquainted with the practical and scientific questions involved in the use of the electric telegraph, and that particular branch known as the telephone-exchange system. He was interested in the Telephone Company; but he hoped he did not give evidence as a partisan, as he thought he could disassociate any interest he had in the Company from questions of fact. From the first it had been the practice to work the electric telegraph by the earth-return system. It had been seriously interfered with in a few cases by external disturbing causes. He knew of a case in Glasgow, where a disturbance of the telephone lines was caused by the running of trains lighted by electricity. The trains ran through a tunnel, and the current was conveyed through a fixed rail and the lamps on the carriages

Can you distinguish at all between the currents used for electric lighting and those used for power in their effect upon telephones?—It would be very analogous in quantity and quality. The same current might be used at one time for lighting purposes, and at another for power; and he saw no reason why the restrictions imposed on one should not equally be imposed on the other. In the summer of last year he accompanied Sir Frederick Bramwell to Leeds to make an inspection of the tramway works there, and he examined carefully the lines, the system of conductors, the mode of carrying the electric current on to the cars, and the engines, dynamos, and instruments. He found that the return circuit was not insulated, and there was a very great disturbance on the neighbouring telephone lines. He attributed the disturbance partly to leakage and partly to induction.

I believe that tramway is worked by a direct current, is it not?—Yes, but the current continually alters. Multiplication of contacts on the car would diminish the disturbance. He thought the disturbance could be prevented by having two conductors and keeping the conductors of the tram-line wholly insulated.

Have you gone into the additional cost of putting an extra line?—I have not gone into it in detail. He had considered the alternative method of working these motors by accumulators; it was a method which had been practised in some cases with success, but whether ultimately it would be commercially satisfactory or not he could not say. In many respects it was to be preferred to insulated conductors. He was of opinion that no one could venture to pronounce in favour or against the use of accumulators in the future.

There is, of course, a counter suggestion that it would be possible for the telephone company to remedy the difficulty by ceasing to use the earth. What do you say as to that?—I think that anyone who passes through the City of London and looks overhead may see that it would be a very great evil to the public if the number of wires were doubled, and it would be necessary to double them to complete the metallic system.

Mr. CRIPPS: You said that the same obligation might be put upon the tramway companies as were put upon the electric lighting companies; would you not rather enlarge that and say that a similar obligation should be put upon the various companies, including the telephone company?—I think not. I think the telephone is so valuable a discovery that it should not be interfered with.

But the difficulty is that the Telephone Company being here no one else can use the earth, is it not?—It would not be disturbed by the Electric Lighting Company. The claim of the Telephone Company was to be allowed to continue the use of the earth as heretofore. He thought the use of the earth for both telephones and telegrams had been unlimited and undisturbed from about the year 1837; it would be a great inconvenience to the public to introduce metallic circuits for all telephones. The electric lighting companies used the gas pipes and water pipes, and if the same thing were done by the tramways, he believed those pipes would be very seriously affected. The telephonic communication was not disturbed by the City and South London Railway, which was not insulated: he admitted the circumstances were different, owing to that railway being enclosed in an iron tube. He did not think that he had expressed the view that there was any considerable practical difficulty in insulating a conductor so that there was no leakage. In the Clapham Junction and Paddington Bill he gave evidence as to the disturbance of the delicate scientific instruments at the laboratory at South Kensington, and the difficulty of maintaining the insulation. It would not be difficult to maintain it to such a degree as not to disturb the telephones, but very difficult to maintain it to such a degree as not to disturb delicate instruments within a short distance of the line of railway. He agreed with Dr. Hopkinson that induction was quite as deleterious to the telephones as leakage. Insulation would deal with the question of induction, because the two insulated conductors would be close side by side. If the metallic circuit consisted of a completely insulated circuit, of which the outgoing and incoming wires or conductors were far apart, there would be disturbance. If the two conductors were insulated side by side, within a few feet of one another, and worked as they would be worked on electric tramways, there would be no sensible disturbance at all upon telephonic lines. The insulation might be quite complete, and yet if there was a varying alternate current through the the system, the induction would be affected. He did not think there would be such disturbance caused by the tramways with two insulated wires side by side as would affect telephones or railway signals. For electric cables he would have the wires underground, but that was not the proper place for a telephone wire, because the telephone was vastly retarded and impeded by the induction which wires underground necessarily experienced. He ascribed the unsatisfactory nature of London telephone service to the great number of wires of all kinds and the great number of disturbances. If the air wires were duplicated it might make the speaking clearer and better for a time, but they would be more liable to interruption by a snow storm. In electric traction, the slot which would be necessary to enable the arm to get to the wire to pick up the electricity should be considerably less than an inch wide; still, it would be open enough for water to get down, but the insulation would not cease if it were kept free from water by proper draining out. Anything which made a connection between the conductor and the bottom of the culvert would bring about leakage. He did not know what the cost of providing an overhead system of insulation at Leeds would be.

In the Folkestone case you gave evidence, and I think you said that £40 a mile spent upon three miles of line, or £120 altogether, would completely insulate the conductors?—I do not remember that expression, but it is about right.

Do you know what was done in that case? The Committee said if the Telephone Company wants to have that insulated they should pay the £120 to have it done, or they should insulate it themselves. Do you know that that was the decision?—I do not know.

Digitized by Google

Do you know that from that day to this the Telephone Company have never done it—they refused to take the order under the circumstances? I do not know.

By Mr. PEMBER: The Glasgow system worked very well as a whole. In the Clapham Junction and Paddington scheme there were several things that were to be feared—vibration and mechanical disturbance, as well as electric disturbance.

In reply to Lord CLIFFORD, who asked if in London there were any electric currents, natural or artificial, other than those created by tramways and electric lighting companies which would be sufficient to interfere with the telephones, Lord KELVIN said he thought the present telephone disturbance in London was chiefly due to the telegraphs, and was partly due to the telephone wires themselves. Any small amount of electricity used for ringing bells and so on would not affect them at all.

By Earl RUSSELL: The use of accumulators on electric launches on the Thames had given them a certain amount of experience, showing that it was not an absolutely impracticable system for tramways, but the cost was not a question with those who used the launches. He did not think any one had yet succeeded in bringing the cost of accumulators down sufficiently to allow of their use for tramways.

The CHAIRMAN said the Committee had considered the question that Mr. Pope had raised about the gas companies, and though he did not suppose they would want to cross-examine all the witnesses, he thought they should be heard in the matter, as they might wish to propose some kind of restriction, which would bring them within the terms of the reference. The case of the water companies was very much the same as that of the gas companies, and probably they could be represented by the same counsel.

Mr. POPE said he should think in all probability that would be so, but he was not instructed on behalf of the Water Companies.

The CHAIRMAN said the Committee thought their case was one, and, therefore, they must be represented by one counsel. They might call their own witnesses to say that they required to be protected in a particular manner.

The Committee then adjourned.

On Wednesday, Mr. Dane Sinclair (Engineer-in-Chief of the National Telephone Company), Sir Frederick Bramwell, Mr. Winterbotham (solicitor to the Company), Dr. Edward Hopkinson, C.E., and Mr. J. S. Forbes (Chairman of the National Telephone Company), gave evidence on behalf of the Telephone Company; and Mr. Aspinall, Engineer of the Lancashire and Yorkshire Railway Company, and Mr. Fletcher, principal Assistant-Engineer of the London and North-Western Railway Company, were examined on behalf of the railway interests.

On Thursday Mr. W. E. Langdon (Electrical Enginner to the Midland Railway Company) and Mr. Spagnoletti (Electrical Engineer of the Great Western Company) also gave evidence, and this closed the case for the Railway Companies; Mr. James Swinburne and Mr. R. E. Crompton were examined on behalf of the Electric Traction Companies.

[*The report will be continued in our next issue.*]

LEGAL INTELLIGENCE.

Elmore's French Patent Copper Depositing Company (Limited).

Three petitions in regard to this case came before Mr. Justice Vaughan Williams on Wednesday. Other proceedings in connection with the same Company had recently come before Mr. Justice Chitty, who had made an order in the matter, which had reference to a proposed arrangement in France, whereby the assets might be realised. Mr. Wilkinson and Mr. Swinfen Eady, who represented petitioning debenture-holders, now withdrew their petitions and acceded to an application by Mr. MacNaughton, representing the liquidators, that the further consideration of the compulsory winding-up petition should be deferred for a month.

Mr. EVE opposed this application on behalf of the unsecured creditors, who, he said, had hitherto received no consideration, and had no means of knowing the nature of the proposed arrangement. They considered that a further adjournment would act prejudicially to their interests unless some independent person were appointed to see that no arrangement was carried out which was not equitable. After some discussion between counsel,

His LORDSHIP suggested that the liquidators and debenture-holders should consent, in the event of his granting an adjournment, that no arrangement should be carried out until it had been brought before him. Unless they consented to that course, he should make the order for the compulsory winding-up at once. He would allow the matter to stand over until Saturday, when, unless some arrangement were agreed to whereby the unsecured creditors might be adequately represented and protected, he should make the order for the compulsory winding-up.

Fowler-Waring Cables Company v. General Steam Navigation Company.

Mr. JUSTICE COLLINS heard this case in the Queen's Bench Division on Wednesday. It was an action for damages for neglect or breach of contract in connection with the carriage and delivery of a drum of telegraph cable. The defendants delivered the goods to the consignee, but without the production of the bill of lading. The consignee had not paid the plaintiffs for the goods, and the latter, failing an attempt made by the defendants to recover possession of them, sued the General Steam Navigation Company for the value of them, £88. 6s. 4d.

After hearing the evidence, His LORDSHIP held that the defendants were liable for the loss sustained, and gave judgment for the plaintiffs for the value of the cable (£88. 6s. 4d.), with costs.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *June* 10, 1893.

Long-Distance Transmission of Power.—American electrical engineers have finally awakened to the great possibilities of electrical power transmission, and this branch is now being taken up in earnest in the United States, following the same lines under which other branches of the electrical industry have been so highly developed. It has, no doubt, been noted that in America the energy of the electrical profession has been concentrated on one object at a time instead of being spread over a great amount of ground. Arc lighting, incandescent lighting, and street railways, have in turn thus been developed, and now force is being brought to bear on the transmission of power. With the exception of the Niagara Falls plant, which, however, can scarcely be considered an American project, no attempt has thus far been made to transmit power over great distances, but rather towards the transmission of a large amount of power over a short distance. There are a number of plants now being constructed to transmit from 1,000 to 3,500 H.P. over distances of from 10 to 40 miles. The General Electric Company has five of these now in course of erection, the largest transmission, 3,500 H.P., being over only 10 miles. In California a plant is now being installed for the transmission of 3,000 H.P., 20 miles, under the guarantee that it will meet the requirements for all varieties of power, and that the efficiency of transmission from generator axle to point of distribution will be at least 79 per cent.

High-pressure Alternators.—A single-phase alternating-current lighting plant of 4,000 volts has been in operation at Portland (Ore.), for several years, and no difficulty whatever has been found in running the generators continuously with this high voltage; and we understand that an order has recently been placed for some new generators for the same plant, to be wound for 6,000 volts. *A propos* of this, Prof. Crocker has in his laboratory a direct-current transformer of 5,000 volts having only 36 bars in the commutator, and is building a similar one for 10,000 volts. From these instances it would appear that the art of insulating for high voltages has considerably advanced.

CORRESPONDENCE.

MUTUAL ATTRACTION OF VACUUM TUBES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: When trying some of the experiments shown the other evening at the Royal Society *soirée* by Mr. Pike and myself, I accidentally found that the attraction between two vacuum tubes far exceeded what theory would expect if due only to static effects, or to the mutual action of one current upon another.

Since that night I have been examining this question further. I have here only a limited supply of apparatus, so that my observations are of a general character, and not so complete as I hope to make them on my return to the country. To sum up the phenomena, which I maintain are truly magnetic, they are:—

1. Two vacuum tubes attract one another strongly.

2. The attraction is almost, if not quite, the same, whether they touch one another along the whole length, or only at their ends,

so: 
or so: 
(The upper tube in these experiments had the current induced in it by the lower tube.)

3. A spiral vacuum tube sucks in a "core" tube like a solenoid does an iron core, and the more the "core" is drawn

Digitized by Google

in the less luminous the "core" tube appears. This lessening of luminosity might be expected. The core tube was not connected to the circuit.

4. When the tubes are placed end to end, so:

they attract one another and stick together; no repulsion takes place, which should occur if the effect were of a "static" nature. One tube *induced*.

5. No. 4 effect remains the same, no matter what positions are given to the tubes.

6. There are many other phenomena requiring further investigations; I, therefore, will not give incomplete and doubtful results.

I believe this subject is new, and if known already to anyone it has not come to light. Being a "bad hand" at producing Papers, for want of time, and perhaps capacity in this respect, leads me to write these few lines in the interest of workers in in the same direction as—Yours, &c.,

DAVID SALOMONS.

49, Grosvenor-street, W., June 15, 1893.

[These experiments cannot readily be explained, whether the phenomena are assumed to be magnetic or static. If the effect is static, the attracting force between the tubes might persist for a few moments after the current is switched off, and it would be interesting to test whether this is the case. Also it is desirable to know the actual magnitude of the force, referred to in experiment (1), with which the "tubes attract one another strongly."—ED. *E.*]

MR. DENNY LANE'S PRESIDENTIAL ADDRESS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: On my return from Belfast I found your article in *The Electrician*. I have to thank you for the favourable terms in which you have spoken of my Address, but in placing me "above the majority of experienced electrical engineers," you have, I think, done them an injustice and attributed to me attainments which I do not yet possess; but which by practical work I may some day approach.

In comparing gas and electric light I endeavoured to hold the balance fairly, but I suppose none of us are free from prejudices. In attributing to gas power of three candles per foot, I calculated no more than can be got by a good Argand burner, without any juggling with temperatures. Such a burner will last for a dozen years or more. It is true that the chimney is sometimes broken, but a new one costs but a few pence against the high price of a new incandescent lamp.

With reference to flat-flame burners which give less light per foot, this deficiency is on the other side equalled by the blackening of glow lamps, and the rapid decline of light whenever the voltage falls, which is, I believe, 6 per cent. for less than 1 per cent. of voltage. Indeed, a fall of several volts reduces the filament to the condition of a red-hot knitting needle. This, of course, should not be the case, but where gas is debited with the carelessness of attendants, surely electricity shall not be held scot-free from the consequences of similar errors.

An old miser of Cologne heard that another miser of Frankfort was more parsimonious than himself, and in order to find out how this could be possible, went on foot to the latter to consult this past-master in niggardliness. He found the man of Frankfort totting his books by the glimmer of a rushlight. When the traveller told the object of his visit, his rival answered, "we can talk as well in the dark," and blew out the rushlight.

Now some of those people who talk of the economy of the electric light must certainly imitate the German miser. There are 1,800 hours in the year from dusk to 11 p.m., and when we hear of only 240 to 365 hours per lamp fixed, I am convinced the economists save their purses at the expense of their comfort. A contemporary scientific journal derides my Irish "figures of speech," but does not assail my figures of arithmetic, and says that Mr. Preece never meant what he said. Be that as it may, he meant other people to believe that current could be supplied at one-third of a penny, for he speaks distinctly of a *supply* unit, and not of a unit generated. If the true function of language be to conceal our thoughts Mr. Preece has admirably succeeded.

I may give as a specimen of the style of the opponents of gas the following paragraph from one of last week's technical journals:—"We contend that a bigger sanitary curse there cannot be than a half-turned-off gas jet. It is a stinking nuisance." Now this, I allege, is absolutely untrue. I have, besides experience extending further back, an intimate connection with gas lighting for 37 years, and I have never found any *lighting* burner, even when turned down to one-tenth of its usual consumption, emit any smell whatever. Of course, a badly-made, or badly-used, Bunsen burner used for heating purposes may "strike back" and produce a most unpleasant smell, but with some burners this is impossible, and with any only possible if the primary supply of air is too large in proportion to the supply of gas, so that the mixture of air and gas burns within the tube instead of doing so at the right place—the upper orifice.

I am no foe of electric light if it be good and fairly cheap; it is not within my feeble powers to make it bad or dear. It has its function, and an important one, to fulfil, but its position will not be advanced by the injudicious advocates who think they whiten their own industry by blackening the character of others whom they should regard as colleagues and not as enemies.

Instead of injuring the cause of electric light, I have done my best to serve it by showing that the cardinal difficulties of storage and distribution can be got over by the employment of sub-stations worked by gas engines. If in endeavouring to aid others, I also try to help myself, I am convinced that this is the form of benevolence which is most likely to be imitated.—Yours, &c.,

DENNY LANE.

72, South Mall, Cork, June 19, 1893.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

TENDERS INVITED.—The Electric Lighting Committee of the County Borough of Huddersfield require tenders for certain materials and labour requisite for laying an electric supply main. Further particulars are given elsewhere, and the specification and forms of tender may be obtained on application to Mr. A. B. Mountain, the borough electrical engineer, Gas Works, Huddersfield, and tenders must be sent in to him by Saturday, July 1st.

——— The City of Glasgow District Lunacy Board require tenders for installing the electric light at the Asylum Buildings at Gartloch. Tenders must be sent in to Mr. Dempster, 318, Parliamentary-road, Glasgow, by Monday, the 26th inst. The Board also require tenders for the supply and fitting up of three Lancashire boilers, for use in connection with the electric lighting. These tenders must also be sent in to Mr. Dempster by the 26th inst. Some further particulars will be found in our advertisement pages.

——— The Committee of the G.U.O.O.F. Central Club require tenders for lamps, wires, fittings, &c., and the fitting up of 82 electric lamps in their premises at Keighley Green, Burnley. Tenders must be in by the 27th inst.

TENDERS ACCEPTED.—The Ealing Local Board have accepted the tender of Messrs. Latimer Clark, Muirhead, and Co., for the erection of machinery in connection with the electric lighting scheme. The following is the complete list of tenders for machinery:—

Clark, Muirhead, and Co., London (accepted)	£7,440
Crompton and Co., London	7,460
Willans and Robinson, Thames Ditton	8,511
Siemens Bros. and Co., London	8,754
Ronald A. Scott, Acton	9,000
W. H. Allen and Co., London	9,300
Electric Construction Corporation, Wolverhampton	9,381
S. Z. de Ferranti, London	10,075
Johnson and Phillips, London	10,160
Woodhouse and Rawson United, London	10,300
Paterson and Cooper, London	10,160
W. T. Goolden and Co., London	10,881
Fowler and Co., Leeds	11,087
Paul Matthew and Co., Dumbarton	12,000

Digitized by Google

APPOINTMENTS.—Mr. G. Roper, of the Board of Trade, has resigned the position of Secretary to the Royal Commission upon Electrical Communication between Lightships and the Shore, and is succeeded by Mr. E. G. Moggridge.

——— Mr. J. J. Walklate, of the South Staffordshire Tramways, and who was identified with the construction of the Walsall Tramways, has been appointed Resident Engineer to the Douglas and Laxey Electric Railway.

APPOINTMENTS VACANT.—The Town Council of Aberdeen advertise for applications for the post of Electrical Engineer to take the more immediate charge of the electric lighting department under the superintendence of the Corporation Gas Works. The salary will be £200 per annum. Further particulars will be found in our advertisement columns, and applications must be sent to Mr. W. Gordon, town clerk, by Friday, the 30th inst.

——— Applications for the appointment of Electrical Engineer at Kingston-upon-Hull have to be sent in to Mr. R. Hill Dawe, Town Clerk, Town Hall, by noon of Thursday next.

——— Applications for the appointment of Electrical Engineer to the Vestry of St. Mary, Islington, London, N., must be sent in to Mr. Wm. F. Dewey, Vestry Clerk, by Wednesday, July 5th.

BANKRUPTCY.—Duncan McGregor, carrying on business at Glasgow, Greenock, London, and Liverpool, under the title of D. McGregor and Co., chronometer and compass makers. A meeting for the election of trustee and commissioners is to be held at the Faculty Hall, Glasgow, on June 27th, at 12, and claims must be in by October 14th.——In the case of William McWhirter, Mr. J. C. Bowes has been elected trustee, and Messrs. A. Campbell, J. H. Carruthers, and J. A. Rudd commissioners. The bankrupt's examination is to be held at Sheriff Guthrie's chambers, Glasgow, to-day (Friday), at 12, and a meeting of creditors is to be held at Messrs. Nairn and Bowes's, 140, Hope-street, Glasgow, on July 3rd, at 2.

REMOVAL.—The International Okonite Company (Limited) have removed their registered offices from 98 and 100, Queen Victoria-street, to their works at Newton Heath, near Manchester. The London business will still be under the supervision of Mr. C. F. Quicke, for whom temporary offices have been taken at 38, Finsbury-pavement, London, E.C. The Okonite Company is undergoing reorganisation, and in the autumn the actual manufacture of okonite in this country will be commenced at their Manchester works In the interim opportunity will be taken for improving the machinery and processes for vulcanised rubber cable, which the Company continue to manufacture at Manchester.

PERSONAL.—Mr. A. G. Sanders, A.I.E.E., who has been on the staff of Messrs. Drake and Gorham for many years as engineer and in charge of the estimating department, has joined Messrs. B. Verity and Sons in a similar capacity in their Manchester business.

LONDON AND LANCASHIRE ELECTRIC AND GENERAL ENGINEERING COMPANY (LIMITED).—This Company which, as previously notified, has recently come under the management of Mr. C. N. Russell, have just concluded several important installations; one at the Holborn Offices of the New York Mutual Life Assurance Company, Bolton Mansions Hotel, Earl's Court, and Lipton's Croydon stores. The British Paper Company have placed the lighting of their Frogmore Mill at Hemel Hempstead in this Company's hands for both arc and incandescent lighting. The mills are to be run night and day. The Company are also busily engaged with installations in different parts of the country, and are busy with their general engineering work, for which new plant has recently been put down.

MESSRS. LAING, WHARTON, AND DOWN.—This Company report that their new office at Manchester, which is under the management of Mr. E. P. Crowther, has in hand a large number of installations of the electric light, including one for the Rochdale Corporation Sanitary Manure Works, another for Messrs. Vickerman and Sons, Taylor Hill Mills, Huddersfield, and for many of the principal banking and business establishments in Manchester and district.

MESSRS. FELTEN AND GUILLEAUME. We have received from Messrs. W. F. Dennis and Co., the agents for the United Kingdom of this firm, their latest general price-list of wire, wire ropes, strand, barb fencing, &c., &c. A large variety of the well-known manufactures of the firm are illustrated, and the descriptions are in all cases accompanied by prices. The firm employs 2,600 hands at the works at Mülheim, and engines of 2,600 H.P. have been put down.

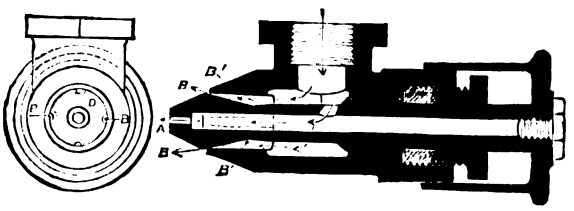
ELECTRICAL POWER STORAGE COMPANY (LIMITED).—This Company has just issued a handsome catalogue and price list of E.P.S. batteries and apparatus. The new list cancels all previous prices, and, in addition to giving complete descriptions and prices of the various types of E.P.S. cells, includes a number of tables which will be found of service to contractors and all persons contemplating the use of batteries in their lighting installations. The cost of the E.P.S. storage batteries, as our readers are aware, has been recently materially reduced, the reductions varying from 15 to 20 per cent. The discounts to the trade remain as before. Copies of the new list will be supplied to the trade on application to the Company's offices, 4, Great Winchester-street, London, E.C. The Company do not give details as to the maintenance of batteries, but offer to send one of their maintenance staff to make an inspection. They then quote a rate which varies between 5 and 15 per cent. We understand that the average rates for existing contracts are under 10 per cent. The rates are quoted as from the original date of supply of the batteries. We are informed that Prof. H. F. Weber, of Zurich, has tested the E.P.S. accumulators at the Union Bank, St. Gallen, which were supplied and erected in 1891, and has found a current efficiency of 97·5 per cent., and an energy efficiency of 82·4 per cent.

INTERNATIONAL ELECTRIC COMPANY.—In consequence of the growth of business, this Company announce that they have removed to more commodious premises at 155, Redcross-street, Barbican, London, E.C., where a larger stock of the Mix and Genest manufactures will be available. The electric light fittings department will be enlarged, and showrooms will be provided for Helios arc lamps, Phœnix carbons, electroliers, brackets, switches, cut-outs, &c. Some of the Company's specialities will be shown working.

BERLINER ELEKTROTECHNISCHE FABRIK (BAUER AND BETZ).—We have received from this firm a price list and particulars of the small electric motors manufactured by them for driving light machinery.

THE TELEPHONE IN AMERICA. It is said that at the present time there are 440,795 miles of wires used for telephone purposes, 552,720 telephones, and 232,140 subscribers to the exchanges, which provide employment for 9,970 persons.

GRANGER'S FORCED DRAUGHT FOR STEAM BOILERS.—The accompanying illustration shows one of the patent steam-and-air nozzles, manufactured by Mr. W. A. Granger, of London. The invention is intended to replace fans and blowers in the production of a forced furnace draught; and is arranged to supply a mixture of air



and steam below the grate, by injection through the nozzle into the ashpit, which is closed. By a special combination of a ring, B', with the ordinary nozzle shown at A and D, an annular orifice, B, is formed around the inner circular orifice; and a higher efficiency is obtained than with either plain annular or plain circular nozzles.

MACHINE TOOLS.—We have received a copy of the new (1893) catalogue, issued by Mr. Alfred Herbert, of Coventry, showing a large variety of machine tools manufactured by his firm. The catalogue contains 50 pages full of illustrations, descriptions, and prices. Firms requiring any description of machine tools should send for a copy of this catalogue.

THE ELECTRICAL INSTALLATION COMPANY.—We have received an attractive little pamphlet entitled "Electric Light and Power" from this Company. It describes the advantages of electric lighting, and gives hints on the arrangement of lamps and switches. A number of illustrations of fittings are given.

ELECTRIC LIGHT ILLUMINATIONS.—Mr. Shippey suggests that coloured glow lamps fixed to a lath may be whirled by a motor, to celebrate the forthcoming Royal Wedding. He informs us that this system has been patented, but that the patents have now expired.

ROYAL AGRICULTURAL SHOW, CHESTER.—This annual show was opened on Saturday last. Among the exhibitors were Messrs. Marshall, Sons and Co., Tangyes, Priestman Bros., Ransomes, Sims, and Jefferies, W. H. Bailey and Co., Crossley Bros., the Blackman Ventilating Company, Robey and Co., W. H. Willcox and Co., Isaac Dixon and Co., Ruston, Proctor, and Co., R. Hornsby and Sons, John Fowler and Co. (Leeds), and many others well known in the electrical and engineering industries. Messrs. Robey and Co. exhibit several of their well-known types of engines, specially suitable for electric lighting work, including a compound Robey engine and locomotive boiler combined, for mill and factory lighting, and a high-speed vertical engine, also specially constructed for electric lighting purposes. The gas and oil engines shown are of the latest design, with special arrangement for regulating speed. The latest type of portable oil engine works on the Otto cycle and is mounted on a strong steel cylindrical tank which

Digitized by Google

contains the cooling water. A chamber containing a week's supply of oil is riveted under one end of the water tank, and the oil is pumped from this tank and forces the gas into an internal vaporiser, where it instantly becomes vapour, and is mixed with the due proportion of atmospheric air and expelled. Messrs. Priestman Bros. also exhibit their popular type of oil engine, varying from 2 to 20 H.P. One of these engines of 20 H.P. was shown driving a Mather and Platt dynamo. This engine has been selected by the United States, New South Wales, and Victorian Governments for electric lighting purposes. Messrs. Priestman Bros. selected the Royal Show for exhibiting the latest improvements in these oil engines, and since 1892 have further developed the marine type for launches, barges, &c., for which special advantages in propelling and reversing gear are claimed. Amongst the exhibits at Messrs. Carrick and Ritchie's stand were included a turbine with horizontal shaft connected direct to a dynamo, which the firm claim is admirably adapted for the lighting of country mansions where water-power is available.

ABERDEEN.—A meeting of the shareholders of the Northern Co-operative Company is to be called to consider the action of the Directors in regard to the electric lighting of the Company's central premises.

BEDFORD.—The Chairman of the Urban Sanitary Authority proposed at the last meeting that a special meeting of that body should be held on Wednesday last to discuss the electric lighting question. The request for tenders which were invited from companies or firms willing to undertake the responsibilities under the Provisional Order had resulted in applications from Mr. F. H. Medhurst, of Cambridge, who makes two propositions; (1) that the Order be transferred to himself; (2) that he undertakes for the sum of £24,000 the work of complete installation. Messrs. C. A. Parsons and Co. offer to put down a plant for £12,000, exclusive of buildings. With each of the above offers plans are enclosed showing the proposed area of lighting. The Bedford Electric Light Company (Limited) offer to undertake and carry out the Order. The Electric Light Sub-Committee, in their report to the meeting on Wednesday, notified their opinion that it would not be judicious to entrust a work of such importance to a private individual, and that Messrs. Parsons and Co.'s proposition does not comply with the terms of the advertisement, and that, therefore, the offer of the Bedford Electric Light Company is the only one they can recommend the authority to entertain.

BERLIN.—The Kaiser has granted his sanction to a proposal of Messrs. Siemens and Halske to construct an elevated electric railway in the southern portion of this city. The line, which is to be of ordinary gauge, is to be completed during 1894. Negotiations are in progress with the view of adopting electric traction as the motive power on the tramway system of Potsdam, near Berlin. The electric tramway between Breslau, Grabschen, and Morgenau recently commenced working.

BIRMINGHAM.—In the autumn of last year the Birmingham Electric Supply Company gave notice to the Corporation of their intention to apply for a Provisional Order extending their system to Edgbaston, and the City Council decided to withhold its consent to such powers being granted until such time as the general question of lighting the Borough by the Corporation itself had received attention. The Company, therefore, withdrew their application, and the Council have had the subject under their consideration, and we understand the result to be that the Corporation will be urged to undertake the supply themselves. In the meantime negotiations are in progress with the Directors of the local Supply Company, and it is not unlikely that certain conditions laid down by the Corporation will be accepted, which may lead the Corporation to postpone taking any steps for the present.

BLACKPOOL.—By the Blackpool, St. Anne's, and Lytham Tramways Bill, which came before the Committee of the House of Commons on Unopposed Bills last week, it is proposed that the Company who are to work the tramway shall be empowered to connect with those already within the area of the Blackpool Corporation, whose tramway is worked by electricity. The tramway is to be eight miles long, and power is included in the Bill to work it either by electricity or animal power. The promoters of the Bill have come to an agreement with the Corporation, and the lease with that body is scheduled in the Act. Clauses are inserted for the protection of the National Telephone Company, and these clauses have been agreed to by that Company. The preamble of the Bill was declared approved.

BOLTON.—The Gas Committee of the Corporation have approved the report of the Electric Lighting Committee upon the electric lighting scheme, and the architect's plans for the generating station have also been approved, and specifications are to be prepared and advertised for.

BREWERY LIGHTING.—The electric lighting of the Ajax Brewery, Richmond (Surrey) has been secured by Messrs. Tickner and Partington. Incandescents will be used for the inner illumination of the buildings, and arcs for the courtyard and roof.

BRIGHTON.—Lord Morley's Committee has passed the Brighton and Rottingdean Seashore Electric Railway Bill, which will now come up for confirmation by the House.

BRUSSELS.—The Brussels Local Administration invites requests for the supply of electric current, the work on the central station having sufficiently advanced to justify the expectation that current can be supplied early in the autumn. A charge of 10 centimes per 100 watts is to be the basis of the charge to be made for the current, with a discount of 5 per cent. upon all lamps which have burnt 1,000 hours per annum. The three-wire system will be adopted.

CANTERBURY.—A letter has been received from the Board of Trade with reference to the proposed transfer of the Electric Lighting Order, to which the Board propose making considerable alterations.

CITY OF LONDON.—On Monday the Committee on Unopposed Bills in the House of Lords passed the City of London Electric Lighting Bill, which authorises the amalgamation of the various undertakings having charge of the electric lighting of the City.—The City Lands Committee will shortly ask leave to extend the electric lighting of the Guildhall to the Museum at an estimated cost of £360.

DEWSBURY.—The Board of Guardians have instructed Mr. Peace, Clerk to the Guardians, to obtain a rough estimate of the cost of fitting up an electrical installation at the Workhouse.

DOUGLAS (ISLE OF MAN).—The Douglas and Laxey Electric Railway is being rapidly pushed forward with a view of a section being opened before the close of the present holiday season. It is constructed on the overhead-wire system; and the contractors for the work are Messrs. Mather and Platt.

EAST LONDON (SOUTH AFRICA).—Tenders have recently been invited for lighting the town of East London by electricity.

GALASHIELS.—The Law and Finance Committee of the Town Council have under consideration a letter from Mr. A. E. Browning, of Edinburgh, with regard to his intention to introduce the electric light into Galashiels.

HOWRAH (INDIA).—The Municipal Commissioners have sanctioned the introduction of the electric light into the principal streets and thoroughfares, and have agreed to allow Messrs. Martin and Co., the contractors, 55 rupees per lamp. This consent is only tentative, and will require renewal after four months.

IRISH LIGHTS.—In the House of Commons on Monday Mr. W. Kenny asked for information as to the application of the electric light as a fixed light at the Old Head of Kinsale, and whether the Board of Trade and the Trinity House had sanctioned the installation of the light. Mr. Kenny further asked that instructions should be given that nothing be done to introduce the electric light until a trial of Mr. Wigham's new gaslight had been completed. Mr. Mundella, in reply, stated that both the Trinity House and the Board of Trade had withheld their sanction to the introduction of the electric light, but that the question of Mr. Wigham's new gas-light trial rested with the Commissioners of Irish Lights.

ISLINGTON (LONDON, N.).—A Bill entrusting the electric lighting of Islington to the Vestry passed the Standing Orders of the House of Commons on Monday last.

LECTURES.—Sir Douglas Galton delivered a lecture on ventilating, heating, and lighting, in the Technical School, Kevin-street, Dublin, on Saturday last. A large number of students were present, and the lecture was a complete success.—On Monday last week a lecture upon "Electro-Medical Eccentricities," illustrated by experiments, was delivered at the Grand Concert Hall, West-street, Brighton, by Mr. H. Newman Lawrence, M.I.E.E.

MADRAS.—As stated in our last issue, the Directors of the Madras Electric Tramways Company have decided to adopt the conduit system, *vice* overhead wires. A system has been devised which, for a slight percentage over the sum required for the overhead system, will provide a mode of traction superior to the latter, especially in being less liable to short-circuiting. The drawings of this system have been received by the Chief Engineer in Madras, and Mr. Faulconer is preparing his plans for the approval of the Municipality and the Local Government. The conduit includes a cast-iron frame about 18in. to 20in. deep on the inside, and about 6in. thick; one of these is placed at intervals of 4ft.; the conductor is pendant from the top of the frame, and by an ingenious arrangement is brought into contact with the grooved trolly which is in direct communication with the wheel-motors. The conductor is so placed that it cannot be tampered with from the outside. Should the conduit require to be opened the removal of a few inches of surface macadam allows of an iron covering to be lifted in sections of 4ft. Square iron gratings at 8ft. intervals permit of the insulators

Digitized by Google

being easily reached by the hand at any time. The conduit is made large enough to allow of lighting and additional power cables being placed within it. By the side of the conduit, between the rails, will be laid either a copper or steel wire conductor, connected at every 4ft. with the rails and with the iron casing of the conductor.

MANCHESTER.—Messrs. Drake and Gorham have received instructions to install the electric light throughout the Manchester and Salford Savings Bank. Incandescents of from 8 to 50 c.p. will be used. The generating plant consists of a 6 H.P. Otto gas engine and a dynamo manufactured by the Electric Construction Corporation, and included in the installation will be a battery of D.P. accumulators, capable of supplying 60 16 c.p. lamps for nine hours.

NANTWICH.—The Local Board have recently discussed the question of adopting the electric light.

NEWTOWN (WALES).—The Local Board have received a letter from Messrs. Rooper and Tozer, suggesting that the electric light be introduced into Newtown. Permission has been granted to the firm to prepare a report on condition that no expense be incurred by the Board for this purpose.

NOTTINGHAM.—There is to be an Exhibition held at Nottingham shortly, and the Victoria Hall is to be lighted throughout by electricity, the plant to be supplied by Messrs. Defries, and the motive-power by the Trent Gas Engine Company, of New Basford.

PLYMOUTH.—Last week the Bill confirming the Provisional Order of the Board of Trade, giving authority to the Plymouth Corporation to construct a series of tramways in development and extension of the present system through the principal thoroughfares of the district, came before the Parliamentary Select Committee on Unopposed Bills. The gauge is to be 3ft. 6in., and the motive-power may be either animal, steam, mechanical, or electrical. The Corporation has power to borrow £24,000, to be repaid in 30 years, the proceeds to be devoted to the construction of the tramways. The Bill was ordered to be reported to the House.

POPLAR.—Royal assent has been given to the Poplar Electric Lighting Act, and the District Board of Works are now in a position to introduce electricity for lighting and power purposes. The matter is under the discussion of the Works Committee.

RICHMOND (SURREY).—The Electric Lighting Committee have recommended the Town Council to accept the resignation of Mr. Shoolbred, C.E., as professional adviser.

SUNDERLAND.—The Highways Committee of the Town Council have received a report from Prof. Kennedy respecting the electric lighting of the town, and have submitted this to the Council with a recommendation that it be adopted, and that Prof. Kennedy be instructed to prepare detailed plans and estimates for the carrying out of the scheme. Alderman Bell urged that no time should be lost in this matter, as their Provisional Order will shortly expire. He was anxious that private persons should be prevented from obtaining powers to supply the light. Prof. Kennedy estimates the cost of providing the necessary plant, &c., for the public installation at £17,000, exclusive of the cost of land, which the Corporation already have at their disposal. The estimate was for a low-tension system, and if it was decided to extend the lighting to Monkwearmouth, an extra expense of £3,500 would be incurred for high tension. With a probable demand equal to 5,600 8 c.p. lamps no loss would result to the Corporation.

SUTTON (SURREY).—The Local Board have received three letters from engineers with regard to the electric lighting of the town, but the General Purposes Committee have deferred making any recommendation on that subject for the present.

SWEDEN.—The Swedish Government appears to be engaged in a not too successful rivalry with the local Telephone Company. When the Government recently determined to undertake an extension of telephonic connection, it was notoriously urged to this course by the fact that unless action was taken by the Government the spirited competition of the Stockholm Telephone Company would result in serious damage to the State Telegraphs. The Stockholm Company is a wealthy body, and has about 7,000 subscribers to its system. The State Department has only about 1,600 subscribers.

TIVERTON.—Messrs. Ford and Son, brewers, are erecting a small station on the River Lowman for supplying their brewery and other premises with the electric light.

VIENNA.—A proposal by Messrs. Siemens and Halske to the Municipal Authorities to light several streets experimentally by electricity has been accepted.

WESTON-SUPER-MARE.—The Inspection Committee of the Town Commissioners have received a letter from the Brush Company offering to submit, free of charge, a scheme for the complete equipment of a central station at Weston, and to send a representative to discuss the matter. The Committee agreed to the suggestion, and a conference is to be arranged.

WORCESTER.—The Highways Committee of the County Council have resolved to conclude an agreement with the City of Worcester in regard to the laying of mains for the electric light from Powick to Worcester. It is essential that the sanction of the County Council should be given before the necessary loan for carrying out the electric lighting scheme could receive the sanction of the Local Government Board.

YARMOUTH.—A Local Government Board inquiry has been held here during the week in reference to the borrowing of £15,0000 by the Town Council for its electric lighting scheme. Considerable local interest is taken in the subject, and strong opposition is threatened. Mr. W. H. Preece, Junr., stated that it was proposed to use the high-tension system, and the light would be supplied to consumers at 6d. per unit. A number of prominent residents notified their intention of taking the light as soon as the Corporation were in a position to supply it.

COMPANIES' MEETINGS AND REPORTS.

Electric and General Investment Company (Limited.)

The following is the report of the Directors of this Company, for the year ended May 31st last, to be submitted to the Fourth Ordinary General Meeting to be held at Winchester House, E.C., on Tuesday next, at 3:30 o'clock :—

The Profit and Loss Account shows a gross profit on the transactions of the year of £11,092. 15s. 4d., and after deducting all standing charges there remains a net balance available for distribution of £6,065. 16s. 5d. An interim dividend has already been paid on the Ordinary Shares for the first six months of the year at the rate of 20 per cent. per annum, and the Directors now recommend the payment of a further dividend upon the Ordinary Shares at the rate of 30 per cent. per annum for the past six months, and a dividend on the Founders' shares of £30 per share. This will leave a balance of £65. 16s. 5d., which the Directors recommend should be carried forward in equal moieties on account of the Ordinary shareholders and Founders. It is proposed to make the dividends payable on July 1st next.

Mr. George Herring has been elected Chairman of the Company in succession to the late Duke of Marlborough, whose death the Directors deeply regret. The Directors who retire this year are Lord Cloncurry and Mr. Braithwaite, who offer themselves for re-election. The Auditors, Messrs. Rait and Kearton, also retire, and offer themselves for re-election.

NEW COMPANIES, STATUTORY RETURNS, &c.

[In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1893, pages 320-348, *&c., &c.]*

CLARKE, CHAPMAN AND CO. (LIMITED).—This well-known business has been registered, under the Joint-Stock Acts, with a capital of £150,000, in £10 shares, as engineers, founders, smiths, and metal workers, of the Victoria Works, Gateshead-on-Tyne.

ELEKTRICITATS-AKTIEN-GESELLSCHAFT VORMALS SCHUCKERT & CO. (NURNBERG).—Under this title a Company has been formed to carry on the well-known works at Nuremberg, founded by Herr S. Schuckert, and conducted for the last year or two under the name of S. Schuckert and Co., Kommanditgesellschaft. The capital is 12 million marks.

ERST UNGARISCHE ELEKTRICITATS AKTIEN-GESELLSCHAFT.—This Company has been formed, with a capital of 6 million marks, to take over the central electric light station at Fiume and that of Messrs. Ganz and Co., at Budapest.

WILLIAM PARNALL AND CO. (LIMITED).—This Company has been registered, with a capital of £30,000 in £10 shares, as iron and brass founders, engineers, makers of engines driven by steam, gas, electricity, or other motive power, electricians, suppliers of electricity, &c., of Victoria-street and Temple-street, Bristol, Manchester, London, and elsewhere.

ORME'S ELECTRIC SIGNAL SYNDICATE (LIMITED).—This Company was registered, on June 15, 1893, with a capital of £7,500, in £1 shares, to carry into effect an agreement between John Orme and Mr. Andrews, for the acquisition of British Patent No. 20,742, 1891, and also a Provisional Specification, entered February 17th, both granted to John Orme for an invention of "Improvements in electrical and automatic signalling," and generally to develop the said inventions. The subscribers, with one share each, are : John Orme, electrical engineer, W. Godbold, C. H. Avey, electrician, W. Powell, N. Mitchell, S. Jennings, and W. M. Grimshaw. The first Directors are to be appointed by the subscribers.

SALT LAKE AND OGDEN GAS AND ELECTRIC LIGHT COMPANY (LTD.).—This Company has been registered with a capital of £300,000, in £1 shares, to carry on in the United States, England, and elsewhere, the business of

Digitized by Google

a gas and electric lighting company, including the manufacture, sale, and supply of gas and electricity for lighting, heating and manufacturing purposes, and to construct, manufacture, and maintain works for receiving, holding, storing, distributing, and purifying gas, electricity, steam, and hot water, and electrical plant and apparatus.

UNITED GUTTA-PERCHA AND RUBBER COMPANY (LIMITED) –This Company has been registered in Edinburgh with a capital of £50,000, divided into 25,000 "A" shares of £1 and 25,000 "B" shares of £1 each, to carry on the business of manufacturers of gutta-percha, indiarubber, &c.

GLOBE ELECTRIC COMPANY (LIMITED).—The statutory return of this Company, made up to March 15, 1892, was filed on May 16th. 5,607 shares have been taken up out of a nominal capital of £10,000, in £1 shares, of which 5,500 were issued to Sir William Vavasour, electrical engineer, of Tadcaster, Yorks. Upon the remaining shares the full amounts have been called and paid. The return for 1893, made up to March 15th and filed May 16th, disclosed a similar state of things, no changes having occurred during the year.

LONDON ELECTRIC SUPPLY CORPORATION (LIMITED).—The annual return of this undertaking, made up to May 31st, has been filed, and shows that 111,000 Ordinary and 48,050 Preference shares have been taken up out of a nominal capital of £1,250,000 divided into 200,000 Ordinary and 50,000 Preference shares of £5 each. The full amounts have been called on these shares, resulting in the payment of £798,890. The sum of £3,740 has been paid on 1,950 Preference shares, which have recently been forfeited.

REUTER'S TELEGRAM COMPANY (LIMITED).—The annual return of this concern, made up to June 14th, has been filed, and 11,839 shares have been taken up, out of a capital of £100,000, divided into 12,500 shares of £8 each. Upon each share taken up the full sum has been called, resulting in the payment of £94,712.

SOUTH AFRICAN LIGHTING ASSOCIATION (LIMITED).—3,000 shares of £10 each in this Company were taken up when the annual return was filed on May 30th last. The full amounts were called and paid on 2,895 shares, while the remaining 105 were issued as fully paid.

SOUTHAMPTON ELECTRIC LIGHT AND POWER COMPANY (LIMITED). The annual return of this Company, made up to May 8th, has been filed. The nominal capital is £30,000, divided into 4,000 Preference and 2,000 Ordinary shares of £5 each. 50 Preference and 708 Ordinary shares have been taken up and the full amounts called. The calls paid amount to £3,685.

SOUTH OF ENGLAND HOUSE-TO-HOUSE ELECTRICITY COMPANY (LIMITED).—WESTERN HOUSE-TO-HOUSE ELECTRICITY COMPANY (LIMITED).—The annual returns of these Companies made up to January 13th, have been filed. Each concern has a nominal capital of £100,000, divided into 19,900 Ordinary and 100 Founders' shares of £5 each. The House-to-House Electricity Supply Company (Limited) claims all the Founders' shares as fully paid, in payment for promotion and registration expenses, and the seven original signatories are the only shareholders figuring upon the recently-filed lists.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The annual return of this Company made up to May 30th has been filed. Out of a nominal capital of £2,445,630, divided into 200,000 Ordinary, 34,563 First Preference, and 10,000 Second Preference shares of £10 each, 88,321 Ordinary, 34,563 First Preference, and 4,669 Second Preference shares, have been taken up. Upon each share the full amount has been called, and the calls paid reach £1,275,530.

CITY NOTES, &c

AFRICAN DIRECT TELEGRAPH COMPANY (LIMITED).—Notice is given that the coupons on this Company's Four per Cent. Mortgage Debentures to bearer, due on July 1st, will be paid on and after that date at Parr's Banking Company and the Alliance Bank, Bartholomew-lane, E.C., and that coupons must be left at the bank for three clear days for examination. Warrants in payment of the interest on the Registered Debentures will be sent out on the 30th inst. The Register will be closed from the 26th to the 30th inst.

AUSTRALASIAN ELECTRIC LIGHT, POWER, AND STORAGE COMPANY (LIMITED).—A meeting is to be held at Messrs. J. H. Duncan and Co.'s, 39, Coleman-street, on July 17th, at 2 p.m., to receive an account of the winding-up of this Company.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).—The coupons of this Company's second issue of Five per Cent. Debentures, due 30th inst., will be paid on and after that date at Parr's Banking Company and the Alliance Bank, Bartholomew-lane, E.C. Coupons must be left three clear days for examination.

CENTRAL LONDON RAILWAY COMPANY.—It is announced that a prospectus, inviting subscriptions for a large portion of the capital of this Company, will be issued in a few days. The Company is formed to construct an electrical underground railway from Liverpool-street to Shepherd's Bush, and the necessary Parliamentary powers have been obtained.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended June 18th were £782, as against £771 for the corresponding period of last year, being an increase of £11. The total receipts for the half-year amount to £21,034, against £19,385 in the corresponding period of 1892, being an increase of £1,649.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—This Company invite subscriptions for 20,000 Preference shares of £10 each, at a premium of £2 per share. The shares form the remaining portion of 40,000 Cumulative Six per Cent. Preference shares, making up the total capital of the Company to £800,000. Interest is to be calculated from the dates of the respective instalments, which are set out in the prospectus to be found in our advertisement columns. Applications for these Preference shares from registered holders of the existing shares in the Company are to be preferentially considered. The prospectus of this issue states that the Company was formed in 1891, and that the first section of the main buildings of the Company's generating station at Bankside is practically completed, and the second section is making satisfactory progress. It is anticipated that at the end of the current year, or early in 1894, provision will be made for the accommodation of boilers and machinery capable for supplying 200,000 8 c.p. lamps. Further freehold property has been acquired adjoining capable of meeting any extensions the Company is likely to require. Machinery is already in course of construction for supplying 140,000 lamps, and the laying of cables with a capacity for 400,000 8 c.p. lamps, in addition to which 2½ transformer sub-stations are either in course of completion or are completed, and will accommodate equipment for the supply of the 400,000 8 c.p. lamps referred to. It is anticipated that by the end of the current year the Company will be supplying current for 100,000 8 c.p. lamps. The present issue is required for extensions. The list of applications will close this day (Friday), at 4 p.m.——Notice is given that all the transfer books and registers of members of this Company will be closed from June 28th to July 12th, both days inclusive.

FROUDE-HURRELL TORPEDO COMPANY (LIMITED).—A first and final dividend of 2s. 4d. is payable at the liquidator's, 33, Carey-street, W.C., any day except Saturday.

HARROGATE.—The proposal to form a private company for the supply of electric current to Harrogate has been abandoned.

HOBART ELECTRIC TRAMWAY COMPANY (LIMITED).—The interest on Coupon No. 3 of the First and Second Mortgage Debentures will be payable on and after July 1st next at the Commercial Bank of Scotland, Lombard-street, E.C.

HUMPHREYS (LIMITED).—The Directors of this Company declare an interim dividend of 7 per cent. per annum on the Preference and 10 per cent. on the Ordinary stock of the Company for the half-year ending May 31st last. £4,000 is added to the reserve fund, which now amounts to £9,000.

PACIFIC AND EUROPEAN TELEGRAPH COMPANY (LIMITED).—The coupons of this Company's Four per Cent. Guaranteed Debentures, due on the 30th inst., will be paid on and after that date at Parr's Banking Company and the Alliance Bank, Bartholomew-lane, E.C. Coupons must be left three clear days for examination.

PANULCILLO COPPER COMPANY (LIMITED).—At an extraordinary general meeting of the Company, on Tuesday, the Chairman (Sir John Pender, G.C.M.G., M.P.) moved the confirmation of the resolution passed on the 2nd inst., directing the voluntary winding-up of the Company. He said the result of the Directors' application to the shareholders to subscribe for Six per Cent. Debentures did not, unfortunately, furnish more than one-third of the amount which would be required to continue the operations, although the Directors took their full complement. He thought there was no doubt that the Company would be reconstructed, and arrangements would be made to enable those who wished to stick to the old concern to do so. The motion was agreed to.

SIR JAMES SIVEWRIGHT, K.C.M.G.—It is rumoured that Sir James Sivewright has been appointed manager of the Netherlands Railway Company.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee have been applied to to appoint a special settling-day in, and to grant a quotation to, the recently-issued £200,000 Four per Cent. (Mauritius Subsidy) Debentures of the Eastern and South African Telegraph Company (Limited).

WEST COAST OF AMERICA TELEGRAPH COMPANY.—The coupons, due June 30, 1893, on the debentures of this Company, will be paid by Messrs. Barclay and Co., Lombard-street. Coupons should be left two clear days for examination.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED.)—The receipts for the two weeks ended June 15th were £2,724, as compared with £2,609 for the corresponding period of last year. The February receipts, estimated at £5,454, realised £5,508.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended June 16, 1893, after deducting 17 per cent. of the gross receipts, payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,867.

WESTMINSTER ELECTRIC SUPPLY CORPORATION.—This Company have issued, under date of June, 1893, their revised rules to be observed by contractors wiring for the electric light in the district served by the Corporation's system.

PORTHCURNO.—A concert was given by the members of the Porthcurno telegraph staff on Saturday last, after which Mr. G. O. Spratt, Assistant Superintendent, was presented with a set of fruit-servers, the occasion being his departure for Gibraltar, where he has been appointed Superintendent in succession to the late Mr. De Sauty. Mr. W. H. Ash made the presentation, and referred to Mr. Spratt's long service in the Eastern Telegraph Company, and to the prominent part taken by him in organis-

Digitized by Google

ing amusements for the Porthcurno staff. Mr. F. C. Judd also referred to Mr. Spratt's past career at Porthcurno. In reply, Mr. Spratt feelingly thanked Mr. Ash and Mr. Judd for their kind appreciation of his services, and extended his thanks to the staff for their universal courtesy and consideration.

REGATTA.—On June 2nd, at Malta, the Eastern Telegraph Company's staff regatta was held, in which the officers of the c.s. "Amber" took part. A very successful and enjoyable day was spent by the competitors and about 250 visitors. After the racing, which consisted of eight events, Mrs. Portelli presented the prizes to the winners.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 789.—Vol. XXXI. FRIDAY, JUNE 30, 1893. PRICE FOURPENCE.
Annual Subscription (U.K.), 19/6

NOTES.

It has been held by the London Electric Supply Corporation that all other metropolitan companies other than themselves would sooner or later suffer from legal proceedings connected with vibration and other nuisance arising from the use of running machinery in densely populated districts. Such difficulties have arisen to a small extent; and one or two cases of damages won by alleged sufferers would stir up all the speculative residents living in the neighbourhood of other stations, sub-transformer stations not excepted. The two cases which are briefly reported elsewhere in our present issue are not calculated to encourage this practice. The estimation of vibration by observing the ripples in a dish of mercury is, if fairly carried out, a sensible method, but fixed conditions should be applied, and the possibility of synchronous vibration with alternating currents or harmonics of mechanical impulses must be avoided. A flash-light photograph of the mercury might be produced in court as evidence. Electric supply companies who have bought up property near their stations have, like rail-way companies who are compelled to take this course, found no difficulty in letting it.

The careful dynamometric and other tests which were at one time carried out by the Royal Agricultural Society, not only added greatly to the interest of their annual shows, but had a most valuable influence on the development of machinery, notably of portable engines. The Cardiff trials are a land-mark in the history of steam-engine construction, and whatever may have been the causes which led to the abandonment of these tests some ten years ago, it is certain that occasional, if not annual, tests of a similar character would be attended with important results. For the first time for several years the machinery section has shown something of its old character, and at the Chester show, which closed last Friday, a very fine collection of gas engines and oil engines was exhibited. Electric lighting has done much to develop and improve both portable steam engines and gas engines for isolated plants, and now that gas engines of 100 H.P. are being built, their use in central stations, either with town gas or with Dowson gas, is sure to follow. Some results of the regular use of a 100 H.P. engine for some three or four months will be found in another column.

The practice of charging for electrical energy supplied during the day-time at a different rate than for that consumed in the evening, is becoming more and more recognised as a mode of equalising the load on a generating station. In America it is supplied at a higher price; in this country the tendency is to supply it at a lower. But the adoption of a cheaper tariff for energy supplied *after* the evening hours of maximum demand, which has just been made at Norwich, comes somewhat as a novelty in methods of charging. In this town consumers taking energy after 8 p.m. on week nights are charged at half the full rate; while on Sundays the lower scale accommodates places of worship by beginning an hour earlier.

After the severe thunderstorms which occasionally break over various parts of the country we receive information of innumerable accidents, and wholesale damage to man, beast and property of all kinds. There is, as a rule, very little originality displayed in these outbursts of electrical activity; but whenever anything of a striking nature occurs we endeavour to find room for it in our Notes, in the hope that some of our readers may make an analytic study of these records with a view to the elucidation of an admittedly recondite subject. Very rarely, as in the instance of a side-flash at Hampstead, the effect of a lightning discharge deserves especial study. We have received from Prof. Lodge an account of a remarkable lightning effect, communicated to him by Mr. Pridgin Teale, the details of which are as follows:—

A short but severe thunderstorm broke over Keighley. At the height of the storm a woman and her eldest daughter were at home. The girl was reading in the living room, her mother having gone into the scullery to fill the kettle, when a vivid flash was succeeded by a tremendous crash. Both mother and daughter were stunned for the time. The mother recovered first and managed to crawl, half-dazed, into the living room, where she found what appeared to be her daughter's dead body lying on the table. The place was filled with dust and wreckage. Several yards of the house gable had been chopped away, and a heavy stone, weighing a hundredweight, had been driven 20 yards with such force as to shatter itself against a wall. Smaller stones and pieces of window glass were picked up 60 yards away. Inside, the house suggested the effects of a dynamite explosion. There was scarcely a whole pane of glass; the walls and ceiling were nearly stripped of plaster and paper, and almost every piece of crockery in the house was more or less damaged. The furniture was splintered or smashed to pieces, one of the window blinds took fire, fire-irons and other pieces of metal were broken, and a kettle, which the mother had in her hand at the moment, was smashed. The lightning appears to have struck the eastern gable, and, after working this mischief, to have left the premises by way of a water-pipe supplying the scullery, which was fused near its junction with the house. In a pigeon-cote near the house a couple of birds were afterwards found dead.

Probably the most remarkable detail in this varied display of energy is the apparent bursting of the kettle in the hands of the woman, who was herself neither killed nor severely

Digitized by Google

injured. Considering the fact that the woman and her daughter were temporarily stunned, as well as the immense damage done by pieces of stonework and other things which were hurled about, the present evidence that the kettle was in the woman's hand when broken does not amount to a demonstration.

The interesting communication, which is to be found in our columns this week, on the action of electricity in accelerating the carburation of iron and steel, and which was originally communicated by M. Moissan to the *Académie des Sciences*, suggests that many of our commercial metallurgical processes may be improved and cheapened by the same agency. Metallurgical processes are, as is well known, usually classified under the wet way and the dry way, and in the domain of the former, electrolysis has long had sway; but the direct and general application of electricity to the latter has only quite recently received attention. That ions of incandescent metal and other materials may pass from one electrode to another seems to be established by the curious intermingling of metals which occurs when two different metals, or two different grades of steel, are electrically welded, while it receives additional evidence from the researches of M. Garnier on the production of blister steel by electrolysis in the dry way. It would not appear that any considerable revolution in steel manufacture is likely to arise on account of these researches, for blister steel forms only a small and comparatively unimportant proportion of the steel production at the present day, the Bessemer and Siemens-Martin types of processes being mainly used. But, as an aid to case-hardening, the process appears to be worth consideration. Moreover, if it is possible, electrolytically, to soak carbon into wrought iron and mild steels, it may not be impossible by the same agency to soak it *out*. In other words, we do not see why the useful operation of producing malleable cast-iron by surface decarburation may not be assisted by electrolysis by the dry method. Should this turn out to be the case, the production of malleable castings for dynamos, which is now very common, could be even more generally practised; and it might probably be found that cast-iron thus treated could safely take the place of wrought-iron in many cases where the latter material is now used.

The speculations of Prof. Armstrong as to the nature of the conditions necessary for the occurrence of chemical change, which will be found in another column, are interesting because they constitute an attempt to correlate facts that have been slowly collected by independent observers, but have not yet been viewed as parts of a coherent whole. When it was first demonstrated experimentally that many substances which unite vigorously under ordinary circumstances, fail to do so when a third material, *e.g.*, water, is rigourously excluded, the knowledge came somewhat as a shock to all but those who were not merely abreast of the then latest developments of chemical theory, but were so far ahead of their fellows as to have turned back for instruction to Faraday. As a contrast to the stir thus made, may be quoted the calm—proper to the announcement of a foregone conclusion—that characterised the reception of Mr. H. B. Baker's recent note on the indifference of HCl and NH_3 to each other when mixed in a perfectly dry state. There has been a shifting of our point of view, and, as always, the isolated phenomenon of one day is the commonplace educational text of the next.

The influence of water in bringing about certain reactions is not unqualifiedly accepted by Prof. Armstrong, on the ground that water is not an electrolyte. Its real function may only be to introduce an impurity, possibly an acid, into the sphere of action. The position thus defined is more easily defended than attacked. Its successful invalidation can only be accomplished by demonstrating that water free from any electrolyte will suffice to induce reaction between two substances such as oxygen and hydrogen, which are inert when dry. Seeing that the difficulty of preparing water pure in this sense is considerable, and that no limit can be at present assigned below which the quantity of electrolyte may be neglected, the contention that water itself is not the real determining factor cannot be gainsaid, and to the hypothesis that an electrolyte is requisite must be conceded, whatever support it may derive from this contention. The suggestion that pure gases should be dielectrics, and that the presence of an electrolyte is necessary to permit of the passage of an electric discharge, serves once again to illustrate the need for more collaboration by chemists and physicists when working at the problems that interest both, in order that each may be a check upon the lapses of the other. For critical experiments, gas from a cylinder labelled "so-and-so" will not do.

In a second communication to the Chemical Society, reproduced in our present issue, Prof. Armstrong has given us the result of his cogitations on the nature of depolarisers. The function of depolarisers to suppress a product of electrolysis at the surface of the electrode is tolerably straightforward and comprehensible. If in so doing it furnish energy supplementary to that owing its origin to other portions of the system, it is to that extent more serviceable. The fact that an endothermic reaction can be induced to take place by the simultaneous and interdependent occurrence of one that is sufficiently exothermic to put the balance of heat units on the right side, is a chemical commonplace, and, in fact, is only a particular instance of the general tendency of energy to become degraded, even though it may have to take a temporary step up for that purpose. Prof. Armstrong's phrase that a trace of nitric oxide might exercise "a fermentative action and condition" upon nitric acid is particularly happy, but the nomenclature-purist will fall foul of it we fear.

Testing Electric Supply Mains.—A letter from Dr. Frölich on Dr. Kallman's article on this subject has been held over owing to pressure on our space this week.

Cable Interruptions and Repairs.—

"Electricity and Biology."—In the July number of the *Humanitarian*, Mr. W. H. Winny writes an interesting article on this subject. Readers will find a general survey of the evolution of scientific opinion as to the relationship of electricity to life from the crudities of the time of Dr. Gilbert to the speculations of the present day upon the influence of electricity on vegetable growth and animal functions of health and disease.

A New Welding Process.—M. Julien, of Paris, has invented a process of electric welding in which the metal to be welded forms one pole of an electrolytic cell containing dilute sulphuric acid. The evolution of hydrogen around this pole by the passage of a strong current is sufficient to isolate the metal from the liquid; when the high resistance causes sufficient heat to raise the metal to white heat. Temperatures up to 4,000°F. can, it is said, be obtained.

Electricity in New Zealand Mining.—In a recent issue our New York contemporary, the *Engineering and Mining Journal*, gives a fine view of the Phœnix Mill, Otago, New Zealand, which is the most important mill in the oldest and best-known gold mining district in New Zealand. This mill was one of the pioneers in the use of electricity for the transmission of power, the plant having been erected in 1884. It consists of two Pelton wheels, receiving water under a head of 180ft., and driving two Brush dynamos. These are connected by a wire line, nearly three miles long, with the motor at the mill.

Who is Tessler?—The following extract from the *Cape Times* may interest our readers:—"Tessler lectured over here a few years ago, and since then he has pursued his investigations much further. His new lecture, delivered in the States, has just been issued, and is being perused with absorbing interest by electricians. Tessler is described to me by a former colleague as an exceptionally fearless man. The first experiments which he made exposed him to the most fearful risks. He literally played with forces of electricity—up to a hundred thousand volts—which might, for aught he knew, have reduced him to a cinder any moment."

The Munsie-Coles Slot System of Electric Traction.—The *Electrical Engineer* of New York describes in a recent issue the Munsie-Coles slot system of electric traction, which is in use on an experimental line at Hartford (Conn.). An insulated cable is tapped at 16ft. intervals into contact boxes. Contact is made by means of a long strip of metal, carried by the car. This strip fills the slot of the conduit, and presses on a grooved roller in each box; the pressure forces a wedged-shaped piece of metal between two spring clips connected with the feeder. The chief apparent advantage of this particular system is the likelihood of high insulation.

Physiological Effects of High Frequency Currents.—The *British Medical Journal* of June 24th contains a short article by Dr. Lewis Jones, exposing the supposed harmlessness of high-frequency currents. He points out, as has been done repeatedly in *The Electrician*, that this wide-spread fallacy arises from erroneous ideas about the magnitude of the currents. He discusses M. d'Arsonval's experiment with a glow-lamp, and shows the errors of his reasoning. An effusion by a Mr. Lynch, in an evening paper of yesterday, contains the following:—"The mere description of Tesla's actual experiments reads like an impossible fairy tale. Those who have felt the 'shock' from a small battery of a single cell will be astonished to learn that Tesla passes through his body a current two hundred thousand times as 'strong,' and yet lives to repeat the experiment."

Marking Meat by Electricity.—The Select Committee of the House of Lords, presided over by Lord Onslow, appointed to inquire into the matter of marking imported foreign meat, had before them on Friday, among other witnesses, Mr. E. Manville, electrical engineer, London, who suggested the accomplishment of the process by means of electricity. He submitted an appliance consisting of a wheel, needled in the circumference, which when connected with an electric-current would, passed over a carcase, make a continuous mark skin-deep; and for a straight line various figures could be substituted, even letters, such as "N. Z.," for New Zealand. Where, as in slaughter-houses provided with the electric light, an electric current could be readily obtained, the cost of the apparatus would be very small; and where there was no such means of obtaining the current the cost would be about £100. Further, the marking could be made an easy, speedy, and, for all parts of the carcase, effective process. The Committee seemed considerably interested in the device.

Effect of a Gaseous Envelope on the Resistance of a Metal.—A short time ago a discussion arose as to the cause of certain small increments in resistance which an ordinary bare copper wire receives on immersion in various gases, experiments upon which had been made by Mr. Fernando Sanford. We have received from Prof. Fessenden a suggestion which would appear to throw some light upon the nature of the phenomenon, at any rate in so far as it relates to gases which have any chemical effect upon the conductor at ordinary temperatures. "If we suppose," writes out correspondent, "that when a wire is placed in a gas-like sulphur dioxide a thin film of a compound of the copper and the gas is formed, only the $\frac{1}{25}$th thousandth of an inch in thickness, it will account for all the phenomena observed by Mr. Sanford. For, as the wire experimented with was 1mm. in diameter, the formation of a layer of this thickness would reduce the cross-section of the copper by 0·2 per cent.," which would correspond with the maximum change in resistance observed by Mr. Sanford. The crucial test of the validity of this explanation is, of course, an examination of the electrical effect, if any, of gases which are known to have no chemical action upon the metal used, and a careful comparison of the observed results with the results obtained when chemically active gases are employed.

Railway Enterprise Development.—We have received introductory pages and two beautifully executed "Woodbury-gravure" plates, being advance proofs of a forthcoming work by Mr. Athol Mayhew, to be published by Messrs. Eyre and Spottiswoode. Some of the objections raised to the introduction of railways, recorded by Mr. Mayhew, may be read with interest in connection with the not unlike feeling in some quarters about electric traction:—

> The country gentry were told that the smoke would kill the birds as they passed over the locomotive. The public were informed that the weight of the engine would prevent its moving. Foxes and pheasants were to cease in the neighbourhood of a railway; the race of horses would become extinct. Farmers were possessed with the idea that oats and hay would no more be marketable produce; horses would start and throw their riders. Even cows, it was said, would cease to yield their milk in the neighbourhood of one of those infernal machines. "What," asked Sir Isaac Coffin in the House of Commons, "was to be done with all those who had advanced money for making and repairing the turnpike roads? What was to become of coachmakers and harness-makers, coach-masters and coachmen, innkeepers, horse-breeders and horse-dealers? Was the House aware of the smoke and the noise, of the hiss and the whirl, which locomotive engines passing at the rate of 10 or 12 miles an hour would occasion? Neither the cattle ploughing in the fields nor grazing in the meadows could behold them without dismay. Iron would be raised in price a hundred per cent., or, more probably, altogether exhausted. It would be the greatest nuisance, the most complete disturbance of quiet and comfort in all parts of the kingdom, that the ingenuity of man could invent."

The Alleged Theft of Blue Prints.—With reference to the statement made by our American correspondent concerning the alleged stealing of blue prints from the offices of the Westinghouse Company, Dr. Bell writes as follows:—"I notice in your issue of June 2nd, in the American Notes, a statement regarding the recent charges made by the Westinghouse Company against the General Electric Company, that seems to call for a few words of explicit denial. The facts are these:—The chief engineer of the Westinghouse Company, under cover of officers, entered the works of the General Electric Company, on the pretence of being a prospective customer, and then exposing himself he had a search made for the alleged stolen blue prints. He found nothing that had the remotest connection with the Westinghouse Company, and he then departed. The plans alleged to have been stolen were those for the utilisation of the water-power at Niagara Falls. As I was responsible for the plans of the General Electric Company for this work, I can state that the allegation was absolutely false. Furthermore, the Cataract Construction Company promptly published a letter denying any similarity between the plans of the Westinghouse Company and the General Electric Company for their work, greater than was found between the

Digitized by Google

numerous plans proposed by other engineers. I feel that in justice to the General Electric Company and to myself as well, the facts in the case should be known."
